Summary of Types

ICs for Television and Radio Receivers

SAA 1008	TV Character Generator
SAA 1020	IC Set for Controlling TV Tuners (Storage IC)
SAA 1021	IC Set for Controlling TV Tuners (Control IC)
SAA 1024	Thirty Channel Ultrasonic Transmitter for Remote-Controlled TV Receivers
SAA 1025	Thirty Channel Ultrasonic Receiver for Remote-Controlled TV Receivers
SAA 1130	Thirty Channel Ultrasonic Receiver with Program Store
TAA 790	Controlled Pulse Generator
TBA 800 C	5 W Audio Power Amplifier
TBA 940	Controlled Pulse Generator for Thyristor Line Output Stages
TBA 950	Controlled Pulse Generator for Transistor Line Output Stages
TBA 950:F	Controlled Pulse Generator for Transistor Line Output Stages in Multistandard TV Receivers
TCA 720	DC Converter
TDA 1035	Sound Channel IC for TV Receivers
TDA 1044	Frame Scan Circuit for TV Receivers
TDA 1053	PIN Diode π Network
TDA 9400	Line Circuit for TV Receivers with Thyristor Line Output Stage
TDA 9500	Line Circuit for TV Receivers with Transistor Line Output Stage

ICs for Electronic Clocks

SAJ 300 R	CMOS Circuit for RF Quartz Clocks with Digital Adjustment and 0.5 Hz Output
SAJ 300 T	CMOS Circuit for RF Quartz Clocks with Digital Adjustment and 64 Hz Output
TAA 780	1.1 V Stabilizing Circuit
TCA 860	Driving Circuit for Clocks with Single Coil Balance Systems

ICs for Motor Vehicles

SAK 215	Pulse Shaper for Revolution Counters
SAY 115	Speedometer and Mileage Indicator
TCA 700 X	Car Voltage Stabilizer

ICs for Electronic Organs

SAA 1004-N	Seven Stage Frequency Divider in I ² L Technique
SAA 1005	Seven Stage Frequency Divider in I ² L Technique
SAA 1005-P	Seven Stage Frequency Divider in I ² L Technique
SAJ 110	Seven Stage Frequency Divider
TDA 0470-D	Gate for Electronic Organs

ICs for Other Applications

SAH 215	Telephone Push-Button IC
TAA 550	Temperature-Compensated Stabilizing Circuit
TCA 350 Y	Delay Line for Analogue Signals
TCA 380	Duplex RF Delay Line
TDD 1605 ...	Voltage Stabilizers for 5 ... 24 V
TDD 1624	
UAA 210	Exposuremeter-IC
ZTE 1.5 ... 5.1	Parallel Stabilizing Circuits
ZTK 6.8 ... ZTK 33	Temperature-Compensated Stabilizing Circuits

Characteristics and Maximum Ratings, Recommended Operating Conditions

The electrical performance of a semiconductor device is usually expressed in terms of its characteristics and maximum ratings.

Characteristics are those properties of the device which can be measured by use of suitable measuring instruments and set-ups, and provide information on the performance of the device under specified operating conditions (at a given bias, for example). Depending on requirements, they are quoted either as typical values, guaranteed values or maximum ratings.

Typical values are expressed as figures or as one or more curves, and are subject to spreads.

Guaranteed values are preceded either by the symbol $>$ (greater than) or $<$ (less than); sometimes the guaranteed spread limits are indicated by two numbers with three dots between them. Occasionally a typical curve is accompanied by another curve, this being a 95 %, or, in a few cases, a maximum spread limit curve.

Maximum ratings give the values which cannot be exceeded without risk of damage to the device. Changes in supply voltage and in the tolerances of other components in the circuit must be taken into consideration. No single limit should ever be exceeded, even when the device is operated well within the other maximum limits. The inclusion of the word "admissible" in a title means that the associated curve defines the maximum ratings. If characteristics and maximum ratings are listed together without a separate heading, then the maximum ratings are identified by the word "admissible".

Because the performance of complex devices such as the ICs listed in this book cannot always be fully described in terms of characteristics and maximum ratings, it is sometimes necessary to describe some performance features by reference to a test circuit, which in many instances is the same as the recommended operational circuit. For some ICs, therefore, a third set of data is included under the heading "Recommended Operating Conditions".

Logic Levels

The logic levels of digital circuits are denoted by the letters "H" (high = maximum positive level) and "L" (low = minimum positive level). If positive logic is used, as usual in connection with bipolar ICs, "H" corresponds to logic "1" and "L" to logic "0".

In connection with MOS circuits the electrical states sometimes are denoted by negative logic, then the state "H" corresponds to logic "0" and "L" to logic "1".

Electrical Designations

The subscripts used in conjunction with the numerous electrical IC data (V - voltage, I - current, R - resistance, f - frequency, etc.) usually denote the associated lead numbers.

If a one-number subscript is used in conjunction with a voltage (V), then this means that the voltage is referred to circuit ground (usually - V_B , 0 V). When a two-number subscript is used, the voltage concerned is that measured between the two terminals, the terminal denoted by the first number usually being positive with respect to the other. Since a dual in line package has 14 pins, the subscript numbers are usually separated by diagonal strokes to reduce the risk of error. A "0" in the third place means, as with transistors, that the other pins of the device are open circuit.

Usually only a single-number subscript is used in conjunction with current. A current indicated as positive is assumed to flow into the pin concerned unless otherwise indicated by arrows on the associated circuit diagram.

Resistors, capacitors and inductors are normally numbered consecutively (e. g. $R1$, $R2$, etc.). If there are two numbers in the subscript (e. g. $R_{14/3}$), then this means that the resistor is connected between correspondingly numbered pins of the circuit.

Assembly Instructions

1. Plastic Encapsulation 50 B 4

a) Devices with vertical pins (suffix "A").

These ICs can be soldered to printed circuit boards so that the bottom of the package rests flat on the side of the board opposite to that carrying the copper conductors.

The pins can be either dip- or hand-soldered. At a soldering temperature of 230 ... 260 °C the soldering time must not exceed 7 sec.

b) Devices with horizontal pins (suffix "B")

These ICs can be soldered to printed circuit boards so that the pins lie flat against the copper conductors with the plastic case projecting into a cut-out in the board.

Hand-soldering must be used. If the soldered joints are spaced more than 1.5 mm (dimension "I") from the case and a soldering temperature of 250 °C is used, then the soldering time must not exceed 8 sec.

Technical Information

2. Plastic TO-116 Encapsulation and similar

As shown in the figure below, the device is fitted to the component side of the board, the pins being soldered to the conductors on the opposite side. A shoulder on each lead ensures that the device cannot be pressed flat against the printed circuit board.

If hand- or dip-soldering at a temperature of 250 °C is used, the soldering time must not exceed 7 sec.

3. Metal Encapsulation similar to TO-5 with 6 to 14 leads

These devices may be mounted in any position. The leads must be bent not less than 1.5 mm from the bottom of the case and then splayed out in accordance with the grid dimensions.

The leads must be cut to the required length prior to the soldering process, which may be performed either by hand- or dip-soldering. The following solder times t_{max} in accordance with the solder temperatures must be observed.

For dip-soldering:

$t_{max} = 5 \text{ sec}$ at 250 °C solder-bath temperature and

$t_{max} = 4 \text{ sec}$ at 300 °C solder-bath temperature.

For hand-soldering:

$t_{max} = 15 \text{ sec}$ with a soldering-iron temperature of 250 °C

$t_{max} = 12 \text{ sec}$ with a soldering-iron temperature of 300 °C

$t_{max} = 8 \text{ sec}$ with a soldering-iron temperature of 350 °C

If MOS components are soldered the soldering temperature should never exceed 300 °C. The solder-bath or soldering-iron and the printed board to be soldered should be kept at the same potential in order to avoid any harmful current flow. It is therefore recommended that the solder-bath or soldering-iron and the leads to be soldered be grounded.

4. Glass Encapsulation DO-35

At a recommended soldering temperature of $\leq 245 \text{ °C}$ the maximum permissible soldering time must not exceed 5 sec. The minimum distance between case and solder point should be at least 4 mm when the component is mounted axis parallel to the p. c. board and 1.5 mm when mounted axis perpendicular to the p. c. board.

Protective Measures for MOS Components

In order to avoid destruction of the components by static discharges or noise voltages, protective structures have been provided at the inputs and outputs. They consist of PN junctions to the substrate which operate in the forward direction in the case of positive voltages; in the case of negative voltages they present a defined non-destructive breakdown. In this case integrated resistors limit the current. Furthermore, in the case of a negative voltage of about -40 V , a field-effect transistor at the input becomes conductive. For higher negative voltages this field-effect transistor constitutes a short-circuit.

All these protective measures behave as RC-networks; their component values depend upon the designed operating speed of the circuit.

If MOS components are not handled in the right way, it can easily happen that static discharges of some thousands of volts from capacitances of over 100 pF reach the connection pins. Despite the above-mentioned protective structures it is suggested therefore that the following recommendations be followed: The floor, the work-benches and the chairs should be provided with a conductive layer. Only metallic transport boxes should be used.

All tools which come into contact with the connection pins (test equipment, soldering-irons, flow-soldering equipment) should be at the same potential as the MOS circuits. Voltage peaks arising from switching operations should be carefully avoided.

MOS components should remain in their original packing (e.g. conductive foam) as long as possible. Before touching MOS components, the packing or the metal container should be touched in order to equalize potentials. Before inserting MOS circuits into printed boards it is imperative to touch the printed board first. MOS circuits should be the last components to be inserted into the printed board and soldered there. The connections of the printed board should remain short circuited until the board is finally used. MOS components must not be inserted or removed from the p. c. board if supply voltage is switched on.

Following these instructions is particularly important in those cases where persons handling MOS circuits wear clothes made from synthetic fibres or wool, or where they wear shoes with non-conductive soles.

Technical Information

Heat Removal from Integrated Circuits

The operation of any integrated circuit involves the dissipation of power with a consequent rise in junction temperature. Because the maximum admissible junction temperature must not be exceeded, careful circuit design with due regard not only to the electrical, but also the thermal performance of a semiconductor circuit, is essential.

If the dissipated power is low, then sufficient heat is radiated from the pins and from the surface of the case; if the dissipation is high, however, additional steps may have to be taken to promote this process by reducing the thermal resistance between the junction and the ambient air. This can be achieved either by pushing a star- or flag-shaped heat dissipator over the case, or by bolting the integrated circuit to a heat sink, or by soldering the pins and the cooling tabs to the copper foil of the p. c. board.

P , the power to be dissipated, T_j the junction temperature, and T_{amb} , the ambient temperature are related by the formula

$$P = \frac{T_j - T_{amb}}{R_{thA}} = \frac{T_j - T_{amb}}{R_{thC} + R_{thS}},$$

where R_{thA} is the total thermal resistance between junction and ambient air. The total thermal resistance in turn comprises an internal thermal resistance R_{thC} between the junction and the mounting base, and an outer thermal resistance R_{thS} between the case and the surrounding air (or any other cooling medium). It should be noted that only the outer thermal resistance is affected by the design of the heat sink. To determine the size of the heat sink required to meet given operating conditions, proceed as follows: First calculate the outer thermal resistance by use of the formula

$$R_{thS} < \frac{T_j - T_{amb}}{P} - R_{thC}$$

and then, by the use of the diagrams shown on next page, determine the size of the heat sink which provides the calculated R_{thS} -value. To determine the maximum admissible device dissipation and ambient temperature limit for a given heat sink, proceed in the reverse order to that described above.

The calculations are based on the following assumptions: Use of a square-shaped heat sink without any finish, mounted in a vertical position; semiconductor device located in the centre of the sink; heat sink operated in still air and not subjected to any additional heat radiation. The calculated area should be increased by a factor of 1.3 if the sink is mounted horizontally, and can be reduced by a factor of approximately 0.7 if a black finish is used.

The curves on the following page give the thermal to ambient resistance of square vertical heat sinks as a function of side length. It is assumed that the heat is applied at the centre of the square.

Copper Cooling Fin

Aluminium Cooling Fin

Steel Cooling Fin

ICs for Television and Radio Receivers

SAA 1008

TV Character Generator

The SAA 1008 is a monolithic integrated MOS circuit in silicon gate technique for displaying a program number (1...16) on the screen of the television receiver, especially in combination with the INTERMETALL ultrasonic remote control receiver SAA 1130.

The fading-in of the program number occurs automatically on the following occasions: with every program command, with the recall command Z1, and with the command "Sequential program change" (see SAA 1130). The duration of the display is determined by an RC network. The numbers are displayed, within a darkened field constituted by 7 x 9 (4 x 9) dots, in the shape of a 5 x 7 dot matrix (ones) or a 2 x 7 dot matrix (tens). Each dot is approximately square and consists of six line sections equivalent to approximately 0.45 μ s. The field area commences at a distance of 114 lines from the upper edge of the picture area and a distance of approximately 86 dots (two-digit number) or 90 dots (one-digit number) from the left margin of the picture. The formation of numbers by the 5 x 7 or 2 x 7 dot matrix can be adapted to comply with customer's wishes by varying the mask. By using appropriate external circuitry it would also be possible to display colored numbers on a field of different color.

The SAA 1008 is capable of processing signals from the ultrasonic remote-control receiver SAA 1130 directly. The control terminals of the SAA 1130 (pins 8...12) are connected to the control terminals of the SAA 1008: the SAA 1008 recognises the program command and the recall command Z1 (see table 1) from the 5-bit word supplied by the SAA 1130. The program outputs of the SAA 1130 are connected to the program inputs of the SAA 1008, and the SAA 1008 recognises the program number from the 4-bit word supplied by the SAA 1130 (see table 2).

Fig. 1: Operating circuit of the SAA 1008

5	Control input C-bit	14	Clock frequency output A_T
6	Control input D-bit	15	Adjustment input E_p
7	Control input E-bit	16	Program input PC
8	Timing input E_K	17	Program input PD
9	Ground, 0, V_{SS}	18	Supply voltage V_{DD}

All voltages are referred to pin 9 (V_{SS}).

Maximum Ratings

Drain voltage	$-V_{DD}$	20	V
Voltage at the other pins	V_n	- 30 ... +0.3	V
Drain currents, pins 11, 12 and 14	$-I_D$	5	mA
Ambient operating temperature range	T_{amb}	- 20 ... +65	°C
Storage temperature range	T_S	- 55 ... +125	°C

Recommended Operating Conditions

Supply voltage	$-V_{DD}$	18 (16.5 ... 19.5)	V
Input voltages at pins 3 ... 7	$-V_{IH}$	< 0.8	V
	$-V_{IL}$	> 4	V
Input voltages at pins 1, 2, 10, 13, 16 and 17	$-V_{IH}$	< 0.8	V
	$-V_{IL}$	> 6	V
Frequency of the internal clock oscillator	f_i	2.2	MHz
	t_b	0.2 ... 1	ms
Pulse duration of signal E_b	t_z	4 ... 12	µs
Pulse duration of signal E_z			

Characteristics at $-V_{DD} = 18$ V, $T_{amb} = 25$ °C

Voltage drop across the output transistors at $-I_O = 1$ mA	ΔV	< 1	V
Current consumption	$-I_{DD}$	28	mA

SAA 1008

The table 1 has been taken from the SAA 1130 data sheet and shows the relationship between the commands and the output code at pins 8...12 of the SAA 1130. An additional column indicates which of the 31 commands in the SAA 1008 triggers the fading-in of the program number. The other commands do not affect the SAA 1008.

Table 1: Commands and output code of the SAA 1130, and their recognition by the SAA 1008

Design and Operation Mode of the SAA 1008

The function of the SAA 1008 will be explained with reference to the various pins.

Pins 1, 2, 16 and 17 — program inputs PA ... PD

To these inputs, information on the selected program must be statically applied in binary-coded form. The required code is shown in table 2. This coded signal is preferably taken directly from the program outputs of the SAA 1130.

Pins 3 ... 7 — A-bit ... E-bit control inputs

By means of the signal applied to these inputs, which is to be coded according to table 1 and supplied preferably directly from the control terminals of the SAA 1130, the fading-in of the program number on the screen of the TV receiver can be triggered. As table 1 shows, the program number display occurs with every program command, with the command "Sequential program change" and with the additional command Z1. What is being displayed in each case is the program number statically applied in coded form to the program inputs.

Pin 8 — timing input E_K

An RC network is connected to this pin, its time constant determining the duration of the program number display. The display is triggered by briefly connecting pin 8 to V_{SS} . The values entered in Fig. 1 for this RC network result in a duration of approximately 2 seconds.

Pin 9 — ground, 0, V_{SS}

Positive terminal of the supply voltage, substrate, reference potential. All voltage levels are related to this potential.

Pin 10 — input E_b for the vertical flyback pulse

To this pin is to be applied the vertical flyback pulse in a shape shown in Fig. 3.

Fig. 3: Shape of the input signal at pin 10

- a) for negative-going pulses
- b) for positive-going pulses

Pin 11 — character output A_Z

Output supplying character information. Drain terminal of an open-drain transistor. The output signal shown in Fig. 4 is obtained if a load resistance is connected between pin 11 and V_{DD} (see Fig. 1). It applies to the first line composing the number "15".

Fig. 4: Shape of the output signal at pin 11

Pin 12 — field-darkening output A_U

Output for the field-darkening operation. Drain terminal of an open-drain transistor. The output signal shown in Fig. 5 is obtained if a load resistance is connected between pin 12 and V_{DD} (see Fig. 1).

Fig. 5: Shape of the output signal at pin 12

Pin 13 — input E_z for the line flyback pulse

To this pin is to be applied the line flyback pulse in a shape shown in Fig. 6.

Fig. 6: Shape of the input signal at pin 13

Pin 14 — clock frequency output A_T

For measuring purposes, the signal of the internal clock oscillator is required externally. In normal operation this is not the case. Pin 14 is then left vacant.

Pin 15 — adjustment input E_p

For the fine adjustment of the clock frequency, a variable direct voltage is applied to this input which is preferably obtained by means of the supply voltage potential divider shown in Fig. 1. The clock frequency determines the dot width within characters to be displayed, and the distance of the display field from the left-hand edge of the frame. Its nominal value is 2.2 MHz. If it is to be set with the aid of a frequency meter, pin 13 must be connected to V_{DD} during the trimming operation.

Pin 18 — supply voltage V_{DD}

Negative terminal of the supply voltage; in television receivers, usually connected to ground.

SAA 1008

Block Diagram of the SAA 1008

Fig. 7 shows a simplified block diagram of the SAA 1008. The frequency of the adjustable integrated oscillator (2.2 MHz) is applied to two clock generators which derive from it a two-phase clock of 2.2 MHz and 314 kHz (2.2 MHz : 7). At output A_T it is possible to measure the oscillator frequency if this terminal is connected to V_{DD} through a pull-up resistor. During the frequency measurement it is also necessary to connect input E_z to V_{DD} .

The input tester examines the 5-bit word supplied by the SAA 1130 to the control inputs A...E and evaluates the combinations listed in table 1 as commands for fading-in the program number. The number displayed is determined by the 4-bit combination applied to the program inputs (see table 2). The appropriate number is called up in the number memory via a decoder. Data for each line are read out serially, the position of the faded-in number on the screen being determined by the X-counter and the Y-counter.

The duration of the display is determined by the integrated timer in connection with the externally connected RC network at pin 8 (see Fig. 1).

Fig. 7: Block diagram of the SAA 1008

IC Set for Controlling TV Tuners

This IC set consists of two integrated MOS circuits. The storage IC functions as a static shift register and has an extremely low current consumption. The control IC SAA 1021 performs the data processing duties. This IC set generates digitally and electronically all the data required for tuner control such as the tuning voltage, the switching voltage for band selection and an additional fine-tuning signal. Realisation of electronic station searching with silent tuning is possible.

In conjunction with with INTERMETALL's ultrasonic remote control system, transmitter SAA 1024 and receiver SAA 1130, and also with the character display circuit — all of which fully compatible with each other — an optimum overall solution has now been achieved to the design complex "remote control, electronic touch-buttons, channel storage, tuner control and program number display in modern color television receivers". The block diagram of Fig. 1 illustrates the interconnection of the ultrasonic receiver IC SAA 1130 to the IC set SAA 1020/SAA 1021 for the tuner control into on complete remote-control and channel selection operating unit.

The designer of a TV set which is equipped with the ICs SAA 1020/SAA 1021 has two possibilities concerning automatic station search and fine tuning. Hereafter, these two possibilities are called Option I and Option II. They are selected by different connection of pin 23 of the SAA 1021.

Option 1:

The TV set can be programmed by an automatic station search operation. Stop signals for interrupting the search operation may be delivered i. e. by the ratio detector of the AFC. During normal TV operation fine-tuning may be adjusted in seven steps, even remote-controlled. The fine-tuning

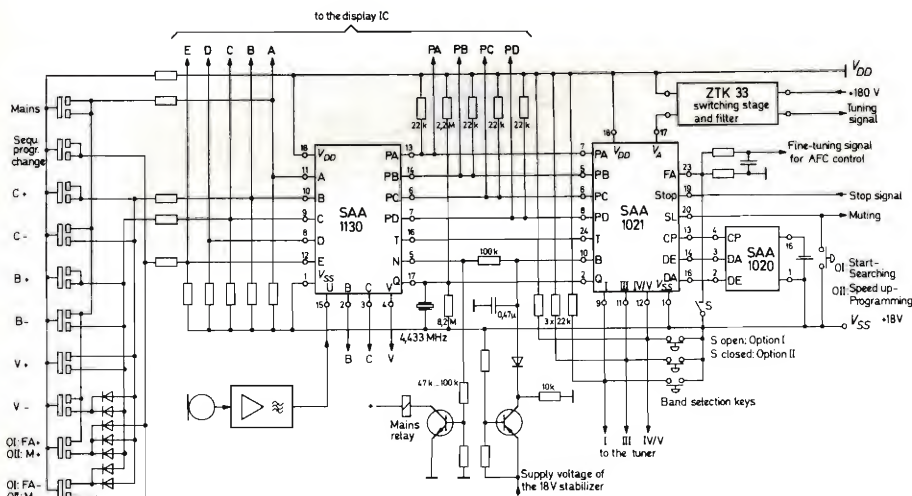

Fig. 1: Control assembly for a remote-controlled color TV receiver

signal may serve as a guide signal for the AFC or it can be superimposed to the basic tuning signal. With that the user of the TV set either can alter the picture sharpness or compensate interferences at weak received stations.

Option II:

In this case the TV set is programmed by a manual station search operation. This is possible with two different speeds and in single steps. The slower speed and the single steps are also remote-controllable. Therefore, a remote-controlled picture correction is also possible, but a fine-tuning signal is not yet disposable. Ratio detector or AFC respectively are not necessary. For this operation mode the fine-tuning output pin 23 must be connected to V_{SS} .

with transistor on the V_{DD} side conducting, at $R_{16/1} = 6\text{ k}\Omega$	$-V_{16}$	> 2	V

Design and Operation Mode of the SAA 1021

explained with reference to the various pins.

Pin 1 — IC substrate, V_{SS}

This pin must be connected to the positive terminal of the supply voltage. All voltage levels are related to the potential on this pin.

Pin 18 — Supply voltage V_{DD}

This pin must be connected to the negative terminal of the supply voltage V_{DD} .

Pin 2 — Quartz terminal Q

This input must be connected to the quartz terminal of the SAA 1130. Here, a quartz crystal including bias voltage divider should be connected if the SAA 1021 is operated without the SAA 1130.

Pin 17 — Tuning voltage V_A

This output issues the digital tuning information by means of which the tuning voltage for the variable capacitance diodes of the tuner is generated with the aid of a switching stage and an RC low-pass filter. The tuning voltage can be set in 3968 steps.

The modulation process is a modified pulse duration modulation whose repetition rate of the pulse pattern remains constant at 558.67 Hz (color sub-carrier frequency divided by 2 times 3968).

Given a tuning voltage rising from zero, we have as the minimum value at the output of the SAA 1021 a low-pulse of approximately 0.46 μ s duration to begin with. This duration subsequently increases in 62 steps of 0.46 μ s each up to approximately 28 μ s. With the 63rd step appears at the output in each period a pulse of 28 μ s duration and a second one of 0.46 μ s duration, the latter again being enlarged step-wise up to 28 μ s duration. This is followed by two 28 μ s pulses and one pulse starting with 0.46 μ s of step-wise increased duration and so forth.

On the one hand, the advantage of this arrangement is that worst-case ripple in the output signal is reduced by the factor of approximately 16 in comparison with ordinary pulse duration modulation. On the other hand, compared with the rate multiplier principle, the number of rising and falling flanks per period is reduced by the factor 64. This excludes falsification of the tuning voltage by the switching flanks.

Pin 9, 11 and 12 — Band inputs/outputs

These three outputs supply data to the tuner and serve as inputs for manual band switching. They are connected to the drain terminals of open-drain output transistors and the transistor which conducts is always the one whose band has been switched on.

If, for example, in the case of new programming a channel key, the band is changed at the receiver's front panel, this is done by using the band selection key (Fig. 1) to connect the associated band output to V_{SS} . This information is at first stored in the SAA 1021 until it is taken over by the storage device SAA 1020 together with the tuning voltage data on completion of a station search upon actuation of a fine-tuning sensor plate (FT, Fig. 1).

SAA 1020, SAA 1021

The band data stored in the SAA 1021 will be rewritten if different band data are read from the storage IC SAA 1020, e. g. when the TV program is changed ultrasonically.

If a fourth band is required, e. g. for cable TV, the signal "all three band outputs blocked" may be introduced instead. For the purpose of manual band selection, all three band outputs must then be briefly connected to V_{SS} .

Pin 20, Option I — Start searching for stations

Programming the channel selection keys — an operation actually to be undertaken only when using the receiver for the first time — can only be carried out at the receiver itself and, in the case of a set designed according to Option I, takes place as follows:

First, a storage location is chosen by actuating a channel key. At this, band and tuning data stored by chance in the storage IC SAA 1020 are taken over into the control IC SAA 1021. Then, the band selection key is depressed which corresponds to the band in which the station to be stored is situated. The key "Start" is now depressed and pin 20 is thus briefly connected to V_{SS} . This initiates the automatic search operation. After this operation has been stopped by a final stop signal the band and tuning voltage data are automatically stored in the SAA 1020. The fine-tuning output is normalised during station searching operation.

If silent tuning (muting) is envisaged, the data required for this purpose can likewise be derived from pin 20. After the key "Start" is released, pin 20 is connected by means of an integrated transistor to V_{SS} potential for the duration of the search run. If, instead of the station responding first because it requires the lowest tuning voltage, the user wishes to select a different station, the key "Start" should be actuated once more which will cause the station with the next-higher tuning voltage to be stored and so forth.

Selecting a channel and start of the station searching operation may be fitted to one respective key via a diode matrix. The speed of the automatic station search run in the three bands is adapted to the slope of the tuner's voltage/frequency characteristic. The entire band IV/V is traversed in 14.2 seconds. In band III, five steps are comprised into a single step, so that the band is traversed within 2.84 seconds, while in band I ten steps are comprised into a single step, resulting in a traverse time of 1.42 seconds.

Pin 19 — Stop of station searching

This pin is used in Option I receivers only and serves as input for the stop signal in connection with an automatic station searching operation. In the non-operative condition, Low-potential must be applied to pin 19 (V_{DD}). The first stop signal briefly switches the pin 19 High (V_{SS}). The trailing edge of the stop signal (HL) changes the direction of the search run, and the leading edge (LH) of the subsequent second stop signal terminates the search. Since the tuning voltage, which is integrated by means of the RC lowpass filter becomes available after the digital information, the first stop signal appears too late, and the tuning voltage slightly overruns the station. Therefore, the stop signal is automatically followed by a correction run in the reverse sense which takes place with

a speed 20 times slower than the search run, so that the discrepancy between digital information and integrated tuning voltage upon a renewed stop amounts to less than half a step. The selected station is stored in the SAA 1020 not before this final stop signal becomes effective.

Stop signals may be derived from a ratio detector or a similar circuit.

Pin 20, Option II — Speed-up programming operation

In the case of a receiver designed according to Option II, the channel selection keys are programmed in the following manner: At first the relevant channel selection key is operated and then the band selection key. Thereafter, the search run is initiated in that the sensor plates $M+$ (manually forward) or $M-$ (manually backward) are touched. Pin 20 connected to V_{SS} at the same time by depressing the key "Fast" will result in a rate of change of the digital output signal at pin 17 of 90 steps per second. By this means a channel interval is traversed within two seconds, which enables the user to stop in good time. If the button "Fast" is not depressed, the tuning information varies at seven steps per second, so that fine tuning of the chosen station becomes possible.

When planning an Option II receiver, the designer can choose between various possibilities concerning the layout of the search run controls. The first alternative has been indicated in the description above. As a second alternative, four tuning keys should be provided, i. e. fast forward, slow forward, fast backward and slow backward. Even a four-function lever resembling a gear lever would be feasible.

The $M+$ and $M-$ commands may be given by sensor plates on the receiver or ultrasonically (commands Z4 and Z5, see the SAA 1130 data sheet). If the $M+$ or $M-$ plates are touched continuously, the digital tuning data at pin 17 are first varied by one step, and this is followed by a pause of about 0.6 seconds, whereupon further tuning steps are produced at intervals of about 0.14 seconds. Thus, three ways of varying the tuning voltage are feasible: a single step if the sensor plate is touched for a time under 0.6 seconds, slow variation by continuous touching of the sensor, and fast variation if the sensor $M+$ or $M-$ and the button "Fast" are actuated simultaneously.

The rate of change of the tuning data is adapted to the slope of the tuner's voltage/frequency characteristic also in the Option II TV receiver in that five steps are comprised into one step in the case of band II, and ten steps into one step in the case of band I.

When used in an Option II receiver the IC set may also be programmed for semi-automatic station searching if an external auxiliary circuit ensures that a changeover from a fast rate of tuning data variation to a slow variation rate is triggered by some stop signal, e. g. derived from the synchronising circuit, when a receivable station synchronises deflection. In that case an automatic stop is obtained near the exact station setting, and fine tuning can be performed manually.

Pin 23 — Option I: Fine-tuning voltage FA

This output delivers fine-tuning information in the shape of a square wave voltage whose pulse duty factor is variable in seven steps and whose frequency amounts to 19 793 Hz. The mean value of the square wave voltage is obtained by means of an RC network. The user of the

SAA 1020, SAA 1021

TV receiver can make fine-tuning adjustments manually, either by touching the sensor plates FA+ or FA- or, ultrasonically, by the commands Z4 and Z5. The pulse duty factor of the fine-tuning square wave voltage is variable between 6 : 1 and 0 : 7.

Manual fine-tuning enables the user to deviate from the automatic tuning. With it he can possibly adjust the picture to more sharpness or weakness in order to compensate unfavourable receiving conditions.

When the automatic station search is started by actuating the button "Start", the fine-tuning voltage is standardised — with a pulse duty factor of the output square wave voltage of 4 : 3 with a period approximately 50 μ s.

After every fine-tuning step, the new information is immediately accepted by the storage device SAA 1020. If the same channel is selected at a later date, the stored fine-tuning level becomes effective again.

Pin 23 — Option II: Option switch-over signal

If this pin is taken to V_{SS} (indicated by the switch S in Fig. 1), then the IC set is programmed for the Option II operation mode.

Pin 24 — Control input T

This input receives control pulses from the SAA 1130. In the Option I mode the fine-tuning data can be altered with these pulses and in the Option II mode the tuning information. Tuning information in the forward direction is varied by pulses of approximately 22 μ s duration and in the backward direction by pulses of about 22 ms duration. At that the speed is seven steps per second.

Pin 21 — Clock output GC

This output delivers a clock signal the frequency of which is approximately 20 kHz and the pulse duration (V_{DD}) about 7 μ s. This signal is assigned for the control of non-volatile MNOS storage devices.

Pin 10 — Blocking input B

In an operating TV set this pin is switched to V_{SS} potential. By switching it to V_{DD} the SAA 1021 will be blocked internally and will not accept any commands for changing band or tuning data. The blocking input receives its control signal (100 k Ω resistor in Fig. 1) from the mains output (pin 5) of the SAA 1130. Thus the SAA 1021 becomes operative only if the mains flip-flop in the SAA 1130 is switched on. Additionally, pin 10 may be equipped with a PNP transistor stage which blocks the SAA 1021 at the correct instant and again releases it delayed only if a sufficient supply voltage is available. This stage in conjunction with the blocking input prevents execution of incomplete reading cycles resulting from an incorrect supply voltage caused by short breakdowns of the mains.

Pin 13 — Storage clock output CP

This push-pull output is low-ohmic and therefore the clock line is insensitive against interferences. This output supplies 288 pulses at a frequency of 138 kHz to the storage IC SAA 1020 for every write or read cycle.

Pin 14 — Data input DE

Via this input the storage IC SAA 1020 supplies data to the SAA 1021.

Pin 16 — Data output DA

This output issues data to the SAA 1020. During any writing or reading cycle the shift register in the storage IC is connected in a closed loop via pins 14 and 16. The entire contents of the data store are circulated once and in each case one 18-bit word will be read or rewritten.

Pins 5...8 — Program inputs PA...PD

The program information will be supplied statically in binary-coded form by the program outputs of the SAA 1130. These outputs are directly connected to the program inputs of the SAA 1021. The table below shows the code. During a read or write cycle, this program information determines the address of the storage device SAA 1020.

Block Diagram of the SAA 1021

Fig. 3 is a block diagram which shows the internal layout of the SAA 1021 and which will be explained in further detail.

The integrated oscillator controls a clock generator. It comprises essentially a 4-by-1 divider and an 8-by-1 divider, generating a 1 MHz and a 138 kHz two-phase clock. The 138 kHz clock signal has a pulse duty factor of 3:5. The faster clock signal clocks the tuning voltage generator and the slower one all the rest of the IC.

The signal generator which generates the tuning voltage at pin 17 consists of a special pulse duration modulator circuit. Its control logic circuit determines the rate of change of the tuning voltage in both operation modes. It recognises stop signals in Option I, generates the forward or backward commands in Option II (controlled by the input T), recognises

SAA 1020, SAA 1021

the start of the station search in Option II and the command "Fast" in Option II (both from pin 20).

The transfer logic effects connection to the storage IC SAA 1020 and consists mainly of a comparator and word counter. In the comparator, the static program address PA...PD is compared with the word counter information. In this way, the address of the 18-bit word in the 16 x 18 bit shift register SAA 1020 is established and becomes effective during a transmission.

The pulse duration measuring unit connected to the input T recognises the duration of the applied signal (approx. 20 μ s or approx. 20 ms resp.). On the strength of this information, the fine tuning data are changed in Option I, and the direction in which the tuning information is varied is established in the Option II mode.

Any errors which may be caused in band switching by the simultaneous actuation of several band selection keys are suppressed by an error recognition circuit connected to pins 9, 11 and 12.

An internal blocking circuit which is connected to the external blocking circuit by an OR gate ensures that a read cycle is automatically initiated in order to call up the channel selected after the supply voltage V_{DD} has been switched on.

SAA 1020, SAA 1021

Design and Operation Mode of the SAA 1020

The SAA 1020 is a static 288-bit shift register capable of storing 16 channel data. It can be directly connected to the control IC SAA 1021 without interface. The clock input is terminated with an integrated resistor $R_{4/1}$ so that the device remains insensitive also if the supply voltage of the control IC SAA 1021 is switched off and its push-pull output turns high-ohmic. The likewise integrated resistor $R_{2/1}$ at the data input limits the voltage swing. The drain connection of an open-drain transistor is the data output.

SAA 1024

Thirty Channel Ultrasonic Transmitter for Remote-Controlled TV Receivers

Monolithic integrated circuit in CMOS technique. The SAA 1024 is intended for remote control systems whereby 30 commands are transmitted by means of 30 different ultrasonic frequencies. The SAA 1025, produced by INTERMETALL, is recommended as a suitable receiver.

The SAA 1024 comprises an oscillator circuit, a variable and a fixed frequency divider, a decoder and a command error protection. Fig. 1 shows the circuit diagram of an ultrasonic transmitter based on the SAA 1024.

Design and Operation Mode

The table shows the 30 ultrasonic transmission frequencies used in the wireless transmission of remote control commands to the TV receiver. These frequencies are derived from the frequency of an SC-crystal controlled oscillator with the aid of a variable frequency divider operating on the blanking principle. This is accomplished in that 1...30 pulses of every 128 out of 2.2168 MHz pulses are blanked out. The variable divider is preceded by a flip-flop which halves the SC frequency. The variable divider is followed by a fixed divider which divides by 50. It reduces the jitter, which is unavoidable when using the blanking principle, to negligible values. The expression for the ultrasonic output frequency is

$$f_u = \frac{x \cdot f_i}{12\,800}$$

wherein $x = 98$ to 127 , i. e. $(128 - 30)$ to $(128 - 1)$ and $f_i = 4.4336$ MHz (sub-carrier frequency). The space between two adjacent ultrasonic frequencies is 346.4 Hz.

Upon actuation of one of the double touch contacts 1 to 30 one of the control inputs $a \dots e$ and $f \dots l$ are simultaneously addressed. In the decoder these input signals are converted into 5-bit words and applied to the variable divider which will then generate the desired ultrasonic frequency.

The command error protection defines any actuation whereby one of the control inputs $a \dots e$ and $f \dots l$ are addressed inaccurately as a command error. Under these conditions the oscillator will not start to operate, and the frequency divider is held in a defined position. The same applies when none of the touch contacts is touched. Consumption under these standby conditions is very low, so that ultrasonic transmitter need never be switched off. The selected frequency appears at the ultrasonic output when the threshold voltage is exceeded at the two control inputs. A threshold voltage hysteresis ensures that AC voltages which may be superimposed on the input voltage cannot falsify the actuation. The RC networks $R3$, $C3$ (Fig. 1) protect the inputs from interference and from damage through electrostatic discharges. These RC networks may be omitted if mechanical actuated contacts are used. In this case the value of resistor $R2$ should be $47\text{ k}\Omega$.

Thirty Channel Ultrasonic Receiver for Remote-Controlled TV Receivers

Monolithic integrated MOS-circuit in silicon-gate technique. The SAA 1025 is intended for remote control systems in which 30 different ultrasonic frequencies are used to transmit 30 control commands. The recommended transmitter is the SAA 1024 produced by INTERMETALL.

The SAA 1025 measures the frequency of the arriving signal by counting the cycles during a fixed measuring time determined by crystal. Evaluation happens only if two succeeding test cycles give the same result. All ultrasonic commands are converted into a coded 5-bit output signal and issued in pulsed form. Nine of the thirty commands are used internally of the SAA 1025 and serve e. g. for controlling the D/A-converter. The further 21 commands are for free application. Sixteen different TV channels are selectable if a 1 out of 16-decoder is connected to the outputs. For storage the channel information, e. g. the integrated circuits SAS 560 S or SAS 570 S may be used.

Signals for controlling three analogue values, e. g. volume, brightness and colour saturation, are stored in the SAA 1025 and continuously delivered in the shape of square wave voltages. The pulse duty factor of these square wave voltages determines the level of the analog value.

Every control command can also be given directly into the IC.

Band width ± 160 Hz

The expression for the ultrasonic input frequency f_v is

$$f_v = \frac{f_t (97 + n)}{12\,800}$$

¹⁾ The command "Normalisation" sets the colour saturation output to a pulse duty factor of 16/15 and the brightness output to a pulse duty factor of 18/13.

Design and Operation Mode

The function of the SAA 1025 will be explained with reference to the various pins.

Pin 1 — ground, 0 V_{SS}

The substrate of the integrated circuit is connected through this terminal with the common positive potential of all supply voltages.

Pin 16, supply voltage, V_{DD}

The supply voltage should be within — 16.5 and — 19.5 V (nominal value: — 18 V). Current consumption is approximately 25 mA.

Pin 5

This pin must be connected to pin 1.

Pin 15 — clock input Q

Pin 15 should be connected via a capacitor to the output of a quartz controlled oscillator containing a colour sub-carrier crystal. The peak-to-peak value of the oscillator output amplitude should be 4...8 V. In the integrated circuit, the quartz frequency is divided by 16. The whole IC operates in synchronism at the clock frequency of approximately 277 kHz thus produced. The accuracy of this frequency determines the accuracy with which the received ultrasonic signals are processed.

Pin 14 — ultrasonic input

The ultrasonic signals are applied to the ultrasonic input via a capacitor. After the arrival of the first ultrasonic pulse, a set-up time of about 23 ms elapses. Then follows a period of measurement with two times 23.1 ms. Then, after an interval of two times 23.1 ms an output pulse of 23.1 ms duration is produced. For a continuous signal, output pulses succeed one another with time intervals of 184.8 ms. During the entire reception period, a resettable counter monitors the cycle time. If there are spaces between two ultrasonic pulses which are either shorter than 18 µs or longer than 36 µs the signal is not evaluated and the signal-processing circuit is reset. After another 15 µs the receiver is ready to operate again. In this way, spurious frequencies above 55.4 kHz and below 27.7 kHz are rendered ineffective.

The table shows how the 30 receivable ultrasonic frequencies are allocated to the various commands. Signals which are either short of 4 pulses or have a surplus of 4 pulses during the measuring time, owing to frequency variations of the transmitter, are still accepted as correct signals. This means that the ultrasonic transmission frequency of 33.9 kHz may fluctuate by ± 0.51 %, and the frequency of 44.0 kHz by ± 0.39 % without causing errors.

Pins 2, 3 and 4 — D/A outputs C, B and V

The outputs C (colour saturation), B (brightness) and V (volume) are the drain pins of the D/A converter output transistors. A square wave output voltage is produced when resistors are inserted between the outputs and V_{DD}. The frequency of these square wave voltages is approximately 8.9 kHz. The pulse duty factor is variable in 30 steps between 1/30 and 30/1. Approximately 115 ms after the onset of an ultrasonic command, the pulse duty factor is advanced by one step. In the case of a continuous signal, further advances follow at intervals of 184.8 ms until the final value is reached. The time needed to traverse the entire range of variation is 5.544 seconds. For the duration of the pulse, an open-drain output transistor is turned on. Its maximum resistance is 1 kΩ.

When the supply voltage V_{DD} is switched on the D/A outputs are normalised with the following pulse duty factors: output colour saturation = 16/15; output brightness = 18/13; output volume = 10/21. The command $n = 4$ (see table) sets output C and B also to a pulse duty factor of 16/15 and 18/13, but this command has no effect to the output V. The command $n = 2$ switches on or off the open-drain transistor at the output V with a delay time of approximately 0.7 s thus acting as a sound On/Off-switch. The sound suppression is also lifted when the TV receiver is switched on after having been switched off.

Pin 10 – option

This terminal allows the operational mode of mains control to be selected. If it is connected to V_{SS} , it will only be possible to block the open-drain transistor at pin 6 (mains off) with the "mains" command. Switching on the mains may be effected by each of the program commands. If pin 10 remains open, then the mains can only be switched on and off by the "mains" command.

Pin 6 – mains switch output

For the purpose of switching the television receiver on or off ultrasonically, the input signal must be available for at least 0.7 seconds. Thereafter, the mains flip-flop is triggered. It controls an open-drain transistor. During the normalisation after V_{DD} is switched on, the mains flip-flop is set in such a way that the output transistor is turned off. The resistance of this transistor is below 1 k Ω when it is turned on. Through pin 6, the mains flip-flop can also be set externally without delay. In that case, pin 6 must be connected to V_{SS} for at least 10 μ s. After switch-off, the mains flip-flop remains locked for 23.1 ms, so that renewed switch-on by the connection of pin 6 to V_{SS} can only take place after the lapse of this time. When the output transistor is turned off, the D/A-converters are locked, i. e. the output signals at pins 2, 3 and 4 cannot be varied.

Pins 7, 8, 9, 11 and 12 – control terminals

Pins 7...12 serve as inputs for commands originating at the television receiver itself and, at the same time, as outputs for ultrasonically transmitted commands. Since the inputs of the MOS circuit have a very high impedance, actuation by means of touch contacts is possible. The leakage currents of the integrated protection diodes connected to the inputs amount to less than 100 nA at room temperature.

A coded command given with the aid of touch contacts is transferred in the same manner via open-source transistors. Characteristics of these output transistors are shown in Fig. 4. Under this condition the SAA 1025 operates as impedance converter.

Fig. 2 shows a recommended circuit for driving pins 7...12 via touch contacts, whilst Fig. 3 illustrates the connection of TTL-ICs to these pins. All the 30 feasible commands must be coded according to the table 1 for addressing the five inputs A...E. Since the leakage currents of the input diodes contained in the TTL circuits (emitter diodes of the multi-emitter transistor) are too high, pins 7...12 of the MOS circuit should be isolated from the TTL inputs by diodes.

While the touch contact is inoperative, the MOS input is pulled towards zero potential by means of the resistor R_1 . The existing leakage currents must not produce a voltage drop across R_1 of more than 0.8 V if a signal-to-noise ratio of 0.8 V is to be maintained with respect to the minimum threshold of 1.6 V. When the touch contact is actuated, current flows through the resistors R_1 , R_2 and R_3 . If the voltage at the input exceeds the threshold, the input transistor starts to conduct and a corresponding signal is transmitted. As the maximum threshold may amount to 2.6 V, suitable dimensioning of the resistors R_1 , R_2 and R_3 will ensure that

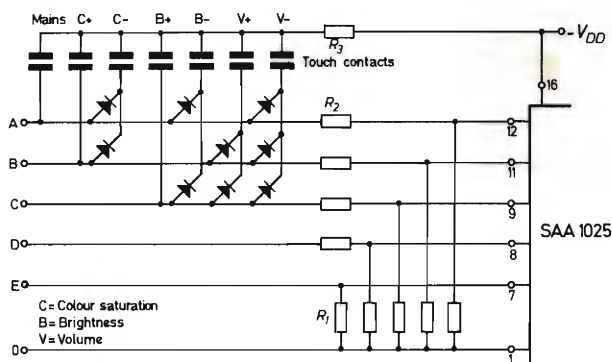

Fig. 2: Arrangement of the touch contacts

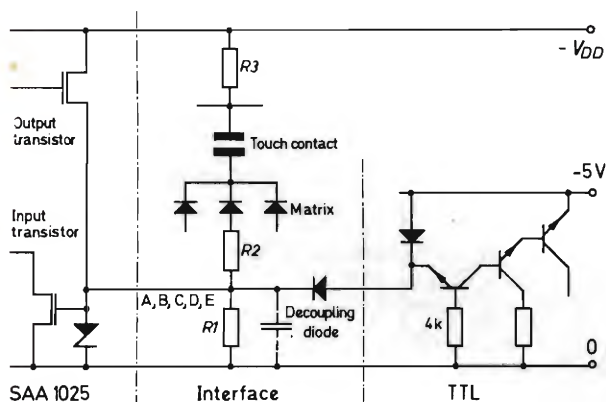

Fig. 3: External circuitry for pins 7...12

an adequate input signal is always available, having due regard to the signal-to-noise ratio.

As the voltage rises, the decoupling diode starts to conduct when a level of approximately -4.5 V has been reached, and this prevents the voltage from rising further. The resistors R_2 and R_3 should be large enough to prevent the current from the TTL input from rising sufficiently high for the TTL circuit to be activated even in the case of a possible short-circuit at the touch contact. This condition can easily be fulfilled in view of the high rating of the protective resistors in series with the touch contact, prescribed for safety reasons.

If necessary, the inputs should be provided with protective capacitors, to provide additional protection against stray fields. If the input threshold voltage is nevertheless exceeded due to isolated surges, for example picture tube flash-overs, such interference is rendered ineffective by an integrated protective logic. An input signal is only recognized as valid if it exceeds the threshold voltage at least once in each of three suc-

SAA 1025

cessive 23.1 ms periods for at least 10 μ s. When this happens, an output pulse of approximately 23.1 ms duration is transmitted after a processing period lasting approximately 46.2 ms. During the output pulse, the output transistor shown in Fig. 3 conducts current, i. e. its resistance falls below 1 k Ω . As a result, the TTL circuit shown in Fig. 3 may be activated, for example.

The output signal transmitted from pins 7...12 acts again upon the input, but this cannot cause interference because the inputs are locked while an output signal is transmitted. If commands are issued both ultrasonically and via the contacts at the television receiver, the direct command will always override the ultrasonic command. The coded signals listed in the table are always transmitted in pulse form by the SAA 1025 no matter whether the command has been issued either ultrasonically or by a contact at the television receiver. This provides the further facility of controlling additional indicating devices.

Fig. 4:

Characteristics of the open-source output transistors at pins 7...12, with admissible power dissipation hyperbolae¹⁾

- b) ---- Limit of spread for $-V_{DD} = 19.5$ V

¹⁾ These hyperbolae refer to a single transistor. All five output transistors may operate simultaneously with the indicated power dissipation.

Block Diagram of the SAA 1025

The block diagram of Fig. 5 shows the internal organisation of the SAA 1025.

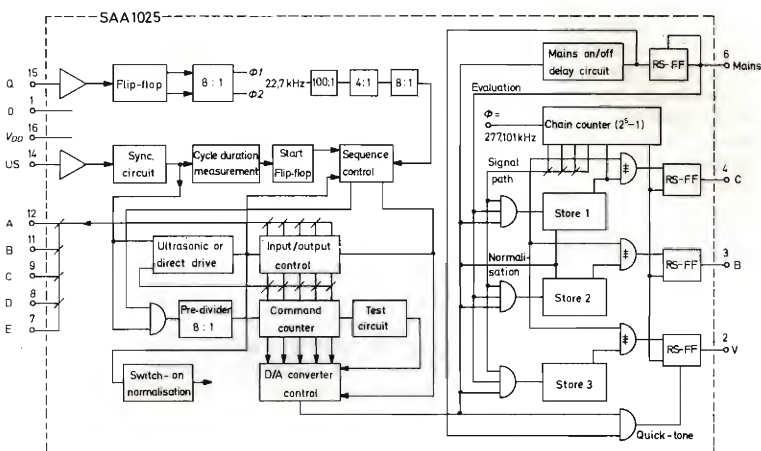

Fig. 5: Block diagram of the SAA 1025

The 4.4 MHz input signal is amplified and drives a clock generator consisting essentially of a flip-flop and an 8 by 1 divider and produces a 2-phase clock signal with a pulse duty factor of 3/8 to 5/8 at 277 kHz. Connected to the clock generator is a 3200 by 1 divider which delivers pulses with a 23.1 ms spacing for control purposes and for determining the measuring time.

The ultrasonic signal is amplified in a preamplifier and then synchronised with the operational clock signal. The signals thus obtained are fed to the circuit which measures the duration of the cycle. If this measurement reveals too long or too short a cycle, the sequence control is reset, and the measuring cycle restarted.

On a second path, an 8 by 1 pre-divider is controlled by the synchronised ultrasonic signals. This divider determines the channel spacing. The command counter is connected to this pre-divider. Together with the test circuit, this command counter forms a 7-bit binary counter. The test circuit ensures that the 5-bit command counter performs three complete counts before the result is evaluated. This excludes the possibility that frequencies which are a multiple or a fraction of useful frequencies produce wrong commands. The command counter comprises a 5-bit register whose contents are compared with the result of the repeat measurement before a command can be evaluated.

All commands are delivered in coded form via the input/output control system to outputs A to E in the form of pulses. The input/output control system ensures also that the command counter is set when commands are produced directly at the input of the TV-receiver.

A switch-on normalisation arrangement ensures that all counters and storage devices are set to the desired initial positions when the supply voltage is switched on. This will only happen when both clock pulses operate correctly. The D/A converter control system recodes the commands, so that the latter can be used to set the storage devices of the D/A converters accordingly.

The basic clock for the D/A output signals is generated by a chain counter which divides the operational frequency by 31. In this way, the available 30 pulse duty factors of the D/A squarewave output signals are determined. The three storage devices consist of five flip-flop stages in each case which can be set in the parallel mode. The information contained in the chain counter is compared with the stored signals by means of exclusive OR elements. In the case of coincidence, the RS output flip-flop is set, and reset every time zero is passed in the chain counter. In this way, three squarewave output signals are obtained having the same frequency determined by the chain counter, their pulse duty factors being fixed by the information contained in the storage device. The latter is changed by parallel conversion in conjunction with information from the chain counter.

An on/off delay is rendered operative upon the arrival of switching commands for the mains flip-flop and when a quick-tone command is issued. The latter blocks the output flip-flop at pin 2.

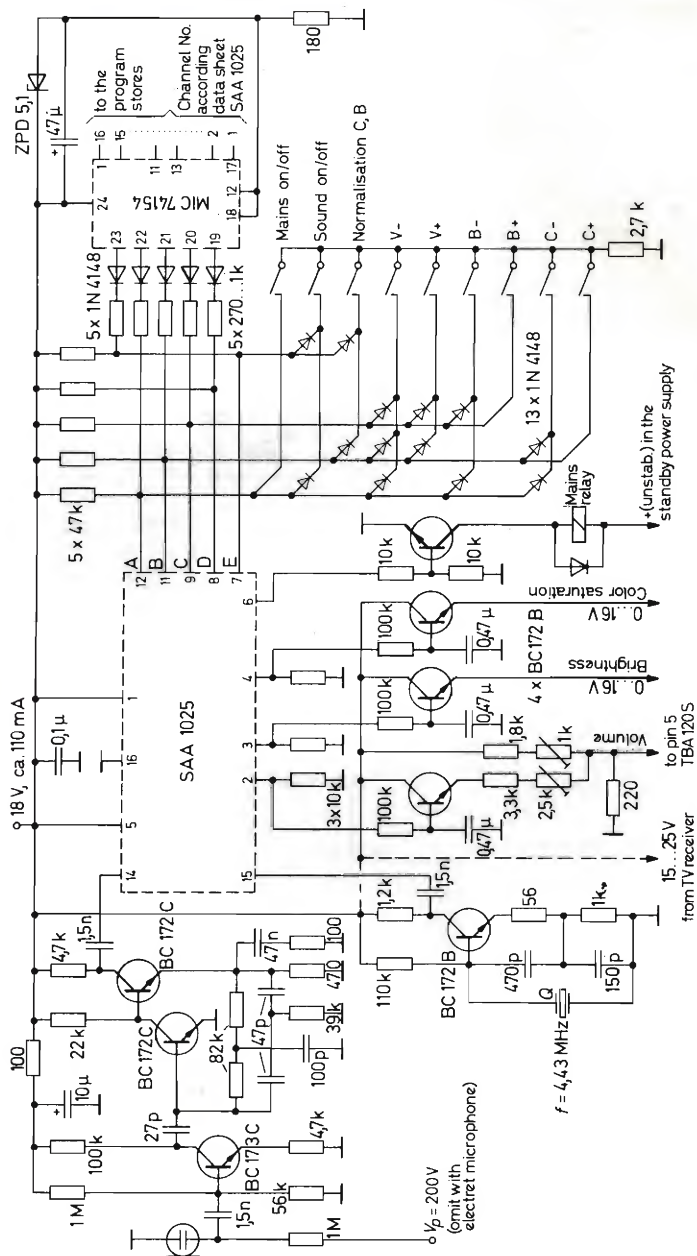

Fig. 6: Complete TV remote control circuit arrangement using the SAA 1025

Thirty Channel Ultrasonic Receiver with Program Store

for television and radio receivers, remote-controlled without cable.

Monolithic integrated MOS-circuit in silicon-gate technique. The SAA 1130 is intended for remote control systems in which 30 different ultrasonic frequencies are used to transmit 30 control commands. The recommended transmitter is the SAA 1024 produced by INTERMETALL.

The 30 control commands can be given not only by ultrasonic transmission, but also by direct inputs to the IC. Furthermore, the additional command "Sequential program change" can be fed to the IC via direct inputs.

The SAA 1130 measures the frequency of the arriving signal by counting the cycles during a fixed measuring time determined by crystal. All ultrasonic commands are converted into a coded 5-bit output signal. The outputs of the SAA 1130 are TTL-compatible.

Signals for controlling three analog values, e. g. volume, brightness and color saturation, are stored in the SAA 1130 and continuously delivered in the shape of square wave voltages. The pulse duty factor of these signals determines the level of the analog value.

The program outputs PA ... PD are provided for driving the IC combination SAA 1020/SAA 1021 by INTERMETALL. This combined device digitally generates and stores the tuning voltages for the variable capacitance diodes of the tuner and the band-switching signals. Moreover, these outputs serve for driving the character generator SAA 1008 which performs the visual display of the program number on the television screen. In the block diagram of Fig. 1, these two possibilities have been indicated.

Explanation of the Commands

The additional command Z1 is provided for the recall of the program number display on the TV screen by means of the INTERMETALL character generator SAA 1008. The additional commands Z4 and Z5 act upon pin 16 (T) through which, via the D/A-converter SAA 1020/1021 for tuner control, fine tuning of the tuner is carried out. The additional commands Z2 and Z3 are available for further applications which may be required.

The TV receiver is switched on — with a delay of approximately 0.7 seconds — if either one of the program selection commands 1...16 or the sequential program change command is given. The sound Off command results in the open-drain transistor at the volume output being blocked, again with a 0.7 second delay. Sound is restored without delay if one of the commands "sound Off", "volume +" or "volume —" is given.

The command "normalisation" has the effect of causing the output signals at the color saturation and brightness outputs to assume the pulse duty factor 32/31.

The center frequencies of the ultrasonic channels indicated by the table 1 are determined in accordance with the clock frequency by the equation given below:

$$f_{us} = \frac{f_i \cdot (97 + \text{US channel No})}{12\,800}$$

Design and Operation Mode of the SAA 1130

The function of the SAA 1130 will be explained with reference to the various pins.

Pin 1 — ground, 0, V_{SS}

Positive pole of the supply voltage. All voltages are referred to this potential.

Pin 18 — supply voltage V_{DD}

Negative pole of the supply voltage

Pins 2, 3 and 4 — analog outputs brightness, color saturation and volume
These three outputs are the drain terminals of the D/A-converter output transistors. A square wave output voltage is produced when resistors are inserted between the outputs and V_{DD} . The frequency of these square wave voltages is approximately 17.5 kHz, the pulse duty factor being variable in 62 steps between 1/62 and 62/1. The given information is contained in the pulse duty factor and thus in the mean value of the potential drop which occurs across the external load resistor. After smoothing by RC networks, direct voltages are obtained whose amplitude determines brightness, volume and color saturation respectively.

Approximately 115 ms after the onset of an ultrasonic command, the pulse duty factor is advanced by one step. In the case of a continuous signal, further steps follow at intervals of 138.5 ms until the final value is reached. The time needed to traverse the entire range of variation is 8.5 seconds. For the duration of the pulse, the open-drain output transistor is turned on, having a voltage drop of max. 0.6 V at 1 mA output current.

When the supply voltage is switched on the output signals of the analog outputs are normalised to the pulse duty factor 32/31. About 0.7 seconds after the onset of the sound Off command, the open-drain transistor at pin 4 is blocked. The sound is restored without delay when one of the commands "sound Off", "volume +" or "volume -" is given. The sound suppression is also lifted when the TV receiver is switched on after having been switched off.

Pin 5 — mains switch output M

Connected to this output is the drain terminal of an open-drain transistor which, in the On-condition of the TV receiver, effects a voltage drop of less than 0.6 V at 1 mA output current. With an admissible output current of -5 mA and a supply voltage of 18 V, a relay can be driven directly from pin 5 if its coil resistance is at least 3 k Ω . However, activation of a driver transistor, a thyristor or a triac is equally feasible. The output transistor is controlled by the mains flip-flop.

If the TV receiver is to be switched on or off either ultrasonically or by direct command, this command will have to be maintained for at least 0.7 seconds before the mains flip-flop responds. If, after the supply voltage V_{DD} has been applied, the SAA 1130 is normalised by its internal On-standardisation, the mains flip-flop will assume a position which results in a blocked output transistor. At the same time, the blocked output transistor causes the D/A-converters to lock, so that the pulse duty factors of the output signals appearing at the analog outputs cannot change while the TV receiver is switched off.

There are three ways in which the TV receiver can be switched on:

by any of the 16 program commands;

by the command "sequential program change" which can only be effected by direct input; or

by connecting pin 5 to V_{SS} for at least 10 μ s.

The TV receiver is switched off by a "mains Off" command. After switch-off, the mains flip-flop remains locked for 23.1 ms, so that renewed switch-on by the connection of pin 5 to V_{SS} can only take place after the lapse of this time.

Pins 8...12 — A-bit...E-bit control terminals

Pins 8...12 serve as inputs for commands originating at the TV receiver itself and, at the same time, as outputs for ultrasonically transmitted commands. Since the inputs of the MOS circuit have a very high impedance, actuation by means of touch contacts is possible. The leakage currents of the integrated protection diodes connected to the inputs amount to less than 100 nA at 25 °C. Fig. 3 shows a circuit arrangement suggested for driving the pins 8...12 by means of touch plates. Fig. 4, moreover, illustrates how a TTL circuit may be driven by pins 8...12.

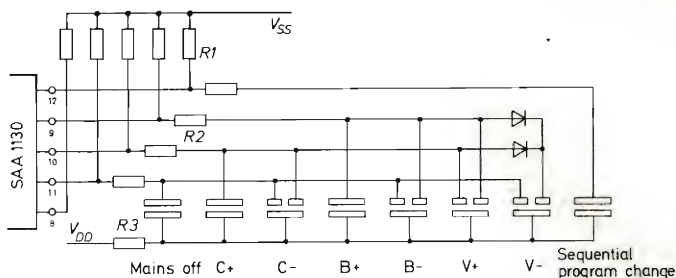

Fig. 3: Driving the control terminals pins 8...12 by touch plates on the TV set

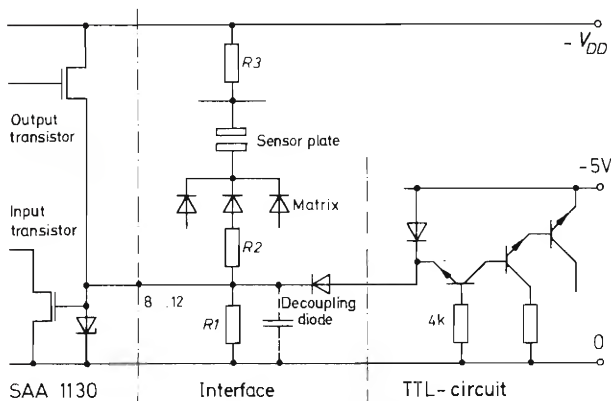

Fig. 4: Diagram showing how the SAA 1130 is connected to a TTL circuit

If all or some of the 31 envisaged commands are to be fed directly to the IC, they will have to be coded according to the table 1 shown on page 54. If such a coded command is issued by an electronic touch plate, it will be issued in the same code as a low-ohmic pulse via the open-source output transistor at pins 8...12. In this mode the SAA 1130 acts as an impedance transformer. The characteristics of the output transistors are illustrated in Fig. 5.

Since the leakage currents of the input diodes contained in the TTL circuits (emitter diodes of the multi-emitter transistor) are too high, pins 8...12 of the MOS circuit should be isolated from the TTL inputs by diodes (Fig. 4). While the touch contact is inoperative, the MOS input is pulled towards zero potential (V_{SS}) by means of the resistor $R1$. These leakage currents must not produce a voltage drop across $R1$ of more than 0.8 V if a signal-to-noise ratio of 0.8 V is to be maintained with respect to the minimum threshold of 1.6 V.

Fig. 5: Characteristics of the open-source output transistors at pins 8...12, with admissible power dissipation hyperbolae. These hyperbolae refer to a single transistor. All five output transistors may operate simultaneously with the indicated power dissipation.

- a) - - - - limit of spread for $-V_{DD} = 16.5 V$
- b) - - - - limit of spread for $-V_{DD} = 19.5 V$

When the touch contact shown in Fig. 4 is actuated, current flows through the resistors $R1$, $R2$ and $R3$. If the voltage drop across resistor $R1$ exceeds the specified V_{IL} minimum value of 4 V, the input transistor conducts, and a corresponding signal is transmitted. Suitable dimensioning of the resistors $R1$, $R2$ and $R3$ will ensure that an adequate input signal is always available, having due regard to the signal-to-noise ratio. As the input voltage rises, the decoupling diode starts to conduct when a level of approximately $-4.5 V$ has been reached, and this prevents the input voltage from rising further. The resistors $R2$ and $R3$ have to be large enough to prevent the current from the TTL input from rising sufficiently high for the TTL circuit to be activated even in the case of a possible short-circuit of the touch plates. This condition can easily be fulfilled in view of the high rating of the protective resistors in series with the touch plates prescribed for safety reasons (see VDE 0860).

If necessary, the inputs should be provided with protective capacitors, to give additional protection against stray fields, see Fig. 4. If the input threshold voltage is nevertheless exceeded due to isolated surges, for example picture tube flash-overs, such interference is rendered ineffective by a built-in protective logic. An input signal is only recognized as valid if it surpasses the threshold voltage within three 23.1 ms cycles for at least 10 μs per cycle. When this happens, an output pulse of 23.1 ms duration is transmitted after a processing period lasting 46.2 ms. During

this output pulse, the output transistor shown in Fig. 4 is conducting. As a result, the TTL circuit shown in Fig. 4 may be activated, for example.

The output signal transmitted from pins 8...12 acts again upon the inputs, but this cannot cause interference because the inputs are locked while an output signal is transmitted. If commands are issued both ultrasonically and via the contacts at the TV receiver, the direct command will always override the ultrasonic command.

The coded input signals listed in the table 1 are transmitted by the SAA 1130 always in the shape of pulses, irrespective of whether the command is issued ultrasonically or directly. It is therefore possible, for example, to drive additional indicating devices by means of the SAA 1130.

Pins 6, 7, 13 and 14 — program outputs PA...PD

From these outputs the information on the selected program can be obtained statically in binary-coded form. The code is shown by the table 2. The output transistors are open-drain transistors whose voltage drop is below 0.6 V at an output current of 1 mA.

TV programs are chosen either selectively (by the commands "Program 1...Program 16") or sequentially (command "Sequential program change"). For sequential program selection, the program information is changed step-wise in the upward sense. If the "Sequential program change" command is given continually, the first change of program takes place after 115 ms, and every further change at 0.7 second intervals. After program 16 has been reached, it is followed again by program 1.

When the supply voltage V_{DD} is applied to the SAA 1130, the program store is automatically set to program 1. If the TV receiver is switched on by the command "Sequential program change", this command is bound to be interrupted after switch-on, before further program-stepping is rendered possible by a new command being issued.

Pin 15 — ultrasonic input U

Ultrasonic signals amplified to at least 500 mV (peak-to-peak) are applied to this input via a capacitor. The integrated input amplifier is biased automatically and has an input resistance exceeding 1 M Ω .

The first ultrasonic pulses arriving at pin 15 are followed by a preparatory period of approximately 23 ms. Then follows a measuring period of twice 23.1 ms. After an interval of twice 23.1 ms, this is followed at the pins 8...12 by an output pulse of 23.1 ms duration, coded according to the table 1. The execution of those commands being processed in the SAA 1130 itself also takes place during these output pulses. If a permanent signal appears at the ultrasonic input, the interval between the output pulses amounts to 138.5 ms.

During the entire reception period, a resettable counter tests the duration of the input signal periods. If the intervals between any two ultrasonic pulses are less than 20.7 μ s or greater than 31.6 μ s, the signal is not evaluated, and the evaluation circuit is reset to its initial state. After about 15 μ s, the ultrasonic receiver's readiness to receive signals is restored. In this way, undesired signals at frequencies below 31.6 kHz and above 48.3 kHz are rendered ineffective.

Pin 16 – input/output T

Pin 16 is an input as well as an output terminal. When the SAA 1130 is tested it serves as input for a blocking signal. If Z4 or Z5 command is issued, the SAA 1130 transmits, in addition to the binary-coded output signal at pins 8...12, a further output signal in the shape of a pulse at pin 16 whose duration, in the case of a Z4 command, is 21.6 μ s and, in the case of a Z5 command, 23.1 ms. These pulses actuate the fine tuning of the tuner via the tuner control IC set SAA 1020/SAA 1021 by INTER-METALL.

Pin 17 – quartz terminal Q

A color sub-carrier crystal (4.4336 MHz) is connected between this pin and V_{SS} . A 5.6 M Ω resistor between pin 17 and V_{DD} determines the bias of the integrated oscillator circuit. The accuracy of the crystal-controlled frequency determines the evaluation accuracy of the ultrasonic receiver.

Block Diagram of the SAA 1130

Fig. 6 is a block diagram which shows the internal layout of the SAA 1130. These will now be explained in further detail.

The integrated 4.4 MHz oscillator drives a clock generator which, essentially, consists of two 2 by 1 dividers and an 8 by 1 divider. This generator produces a 1 MHz and a 277 kHz two-phase clock signal. The slow clock has a pulse duty factor of 3/5. Its purpose is to synchronise the whole IC, except the D/A-converter and the cycle counter.

The 6 400-by-1 divider produces the stepping clock signal for the operation control. This unit is the central control unit of the ultrasonic receiver. It determines the measuring times and the entire time sequence of command evaluation.

The ultrasonic signal is fed to a preamplifier via pin 15 and then synchronised with the operational clock signals. The measurement of the cycle time takes place by resetting a counter clocked with a 1.1 MHz frequency. If the counter is reset before a predetermined count has been attained, then the ultrasonic frequency was too high. If the counter reaches its final position, then the ultrasonic frequency was too low. In either case the evaluation of the ultrasonic signal will be interrupted at once, i.e. the operation control unit is reset and the test cycle recommences.

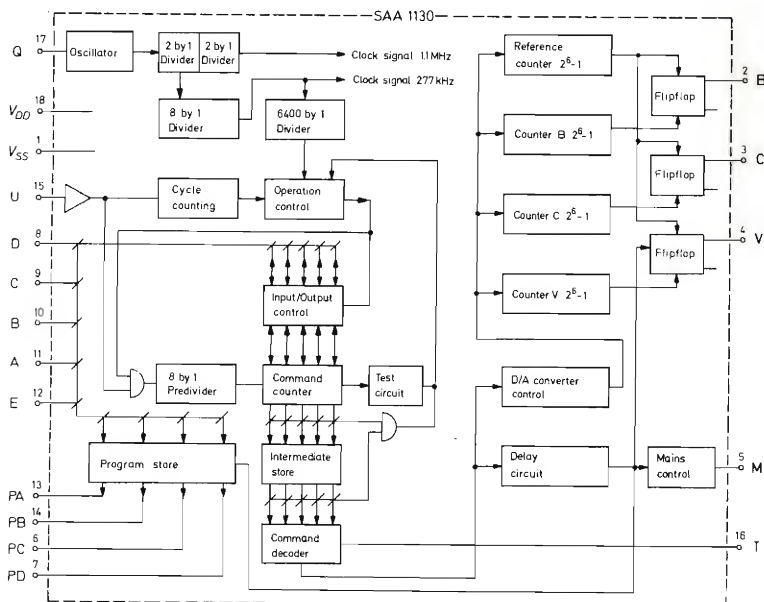

Fig. 6: Block diagram of the SAA 1130

The synchronised ultrasonic signal is also taken to an 8-by-1 divider. The 320 Hz spacing between ultrasonic channels is determined by this divider, to which the 5-bit command counter and a 2-bit test counter are connected. This test circuit ensures that the command counter will have performed three counts before the result is evaluated. The count of the command counter is stored in the intermediate store after the first counting operation. After the second counting operation, the new count of the command counter is compared with the information contained in the intermediate store. Evaluation takes place only if parity has been achieved.

All commands which have been issued are transmitted in pulsed shape to outputs A...E (pins 8...12) via an input/output control unit. In the case of direct feed-in, this control unit ensures that the command counter is set correctly.

The program store is provided in the form of a settable 4-bit binary counter. In the standby condition, program information is stored.

The D/A-converter is a pulse width modulator. It consists of four chain counters, three RS flip-flops and the control unit. The chain counters divide the high clock frequency (1.1 MHz) by 63. In this way, the 62 feasible pulse duty factors of the square wave output signals at the analog outputs (pins 2...4) are being determined. A chain counter and an RS flip-flop are allocated to the three outputs in each case. In the normalised mode, the zero passage of the reference counter is displaced by 32 counts in comparison with the zero passages of counters B, C or V. If the reference counter reaches zero, all the output flip-flops are set in such a way that the output transistor conducts. On zero passage of the counters B, C or V, the respective flip-flop is reset and the output transistor blocked. At the output, a square wave voltage with a pulse duty factor of 32/31 is thus created. If this factor is to be varied, then the associated counter is held back by one clock cycle while the reference counter and the other two chain counters continue their count. Owing to this retardation, the counter concerned reaches zero passage one clock cycle later, and the pulse duty factor at the output will now be 33/30. A variation of the pulse duty factor in the other sense is obtained in that the relevant chain counter completes its count and the reference counter and the other two chain counters are held back by one clock cycle. In that case the pulse duty factor of the associated analog output will be 31/32.

The delay circuit is activated in the case of the change-over commands for the mains flip-flop and in the case of a quick-tone command.

An internal normalisation arrangement ensures that all counters and storage devices are reset to the desired initial position when the supply voltage V_{DD} is switched on.

Controlled Pulse Generator

Monolithic integrated circuit for pulse separation and line synchronization in television receivers.

The TAA 790, comprising the sync separator with noise suppression, the phase comparator, a switching stage for automatic changeover of noise immunity, and the line oscillator, is designed to replace the shaded part in the block diagram of a conventional television receiver (see Fig. 1). The feedback of the reference pulses from the line transformer to the phase comparator is no longer required, since the control loop for the line synchronization is closed within the TAA 790. Thus synchronization is not dependent on the shape of the flyback pulse.

TAA 790

Design and Operating of the TAA 790.

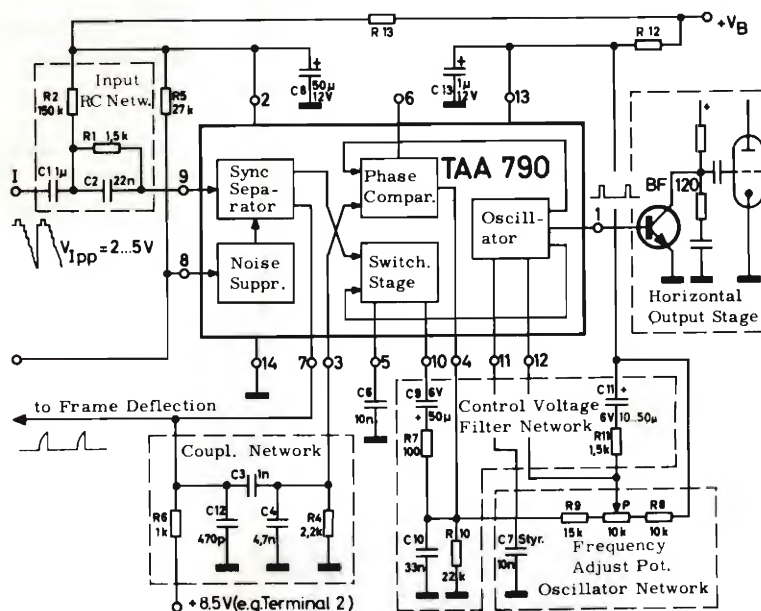

Fig. 8: Operating circuit

The two-stage sync separator separates the synchronizing pulses from the composite video signal. A noise suppression signal may be applied to pin 8. In the phase comparator, the differentiated output pulses of the sync separator are compared with a signal derived from the oscillator. The output signal of the phase comparator is connected to the control input of the oscillator through a filtering network, whose parameters are changed depending on the state of synchronism. A switching stage changes the filtering network to large bandwidth operation in the non-synchronous state, which facilitates pull-in and ensures noise-free operation in the synchronous state. With the addition of a transistor BF 120 the output pulses of the TAA 790 can be used to drive a line output tube.

The positive supply voltage is connected via series resistors to pins 2 and 13, the negative pole to ground pin 14. A filtered voltage (filtering network R_{13}, C_8) is required at pin 2. The voltage at pin 13 is stabilized by an internal Zener diode.

The input video signal (pos. sync pulses) is fed to pin 9 of the IC through an RC coupling network C_1, C_2, R_1, R_2 . The base of the noise suppression stage is connected to pin 8 and is held "ON" by a current supplied by resistor R_5 . If noise suppression is required, an additional inverted video signal (neg. sync pulses) must be applied to pin 8.

The sync separator output is connected to pin 7. The separated pulses are available at resistor *R6*. They are then fed to the integrating network of the vertical amplifier and through coupling filter *C3*, *C4*, *C12*, *R4*, *R6*, to pin 3 of the phase comparator (reference frequency input). The comparison signal is internally fed from the oscillator to the phase comparator.

The oscillator capacitor *C7* (Styroflex type with $\pm 5\%$ tolerance) is connected to pin 11. A DC control voltage is needed at pin 12. This control voltage is adjustable by means of potentiometer *P*. It is obtained from the stabilized voltage at pin 13 by means of the voltage divider *R8*, *P*, *R9* and *R10*. The control signal synchronizing the oscillator is supplied from the phase comparator through pin 4. It is fed into the voltage divider at junction point *R9*, *R10*. From pin 1 the output signal of the oscillator is available as a rectangular pulse signal. This signal serves to drive the horizontal amplifier.

Pin 6 is intended for the adjustment of the phase shift t_v (see Figs. 4... 7) and accordingly the horizontal position of the image on the screen of the picture tube. A resistor connected between pins 6 and 13 increases t_v and displaces the image to the right (see Fig. 5). A resistor connected between pins 6 and 14, displaces the image to the left, t_v becoming smaller or negative (see Fig. 6). A change in t_v causes the same change in the output pulse duration, t_i .

The switching stage has an auxiliary function. When the two signals supplied by the sync separator and the oscillator respectively are in synchronism, pin 10 is switched from high to very low resistance to ground. Thus an additional *RC* network *R7*, *C9* is paralleled to the smoothing capacitor *C10*, so enlarging the filter time constant. By this means the control signal generated in the phase comparator is smoothed, so providing noise-free operation in the synchronous state.

TBA 800 C

5 W Audio Power Amplifier

The TBA 800 C is a monolithic integrated class B push-pull power amplifier in a 12-lead dual in-line plastic package with leads specially formed to facilitate automatic insertion of the device in suitable punched printed circuit boards. The external cooling tabs enable 2.5 W power output to be achieved without external heat sink and 5 W power output using a small area of the printed circuit board copper as a heat sink.

The TBA 800 C provides 5 W power output at 24 V supply voltage 16 Ω load impedance and works with a wide range of supply voltage (5 to 30 V). It gives high output current (up to 1 A), high efficiency (70% at 4 W output), very low harmonic distortion and no cross-over distortion.

TBA 800 C

Fig. 11: Operating circuit with the load connected to the positive pole of the supply voltage. This configuration entails a smaller number of external components and can be used at low supply voltages.

Fig. 12: Operating circuit with the load connected to the negative pole of the supply voltage (ground). There is no bootstrap connection and hence there is a greater loss of potential output swing. This circuit is only for use at high supply voltages.

In the absence of "bootstrap", the reduction in the upper part of the wave is greater than in the lower part. If pin 3 is left open circuit, this automatically inserts two integrated diodes (internally connected to pin 3, see Fig. 17) and this enables a symmetrical wave to be obtained at the output.

For this circuit an excellent supply voltage ripple rejection is obtained by connecting a capacitor (10 to 100 μ F, 25 V) between pin 7 and ground.

Fig. 13:
Distortion factor versus output power in the circuit Fig. 12

Fig. 14:
Output power versus supply voltage in the circuit Fig. 12

Fig. 15: Operating circuit. The bootstrap capacitor of 100 μF between pins 12 and 4 enables the same electrical characteristics as circuit of Fig. 1 to be achieved. For low supply voltage operation, e. g. 9 to 14 V, a 150 Ω resistor is connected between pins 1 and 4.

For this circuit an excellent supply voltage ripple rejection is obtained by connecting a capacitor (10 to 100 μF, 25 V) between pin 7 and ground.

TBA 800 C

Mounting Instructions

The tabs on the TBA 800 C can be used to conduct away the heat generated in the integrated circuit so that the junction temperature does not exceed the permissible maximum temperature of 150 °C. At an output power up to 2.5 W the tabs themselves are sufficient large. At higher output power these tabs have to be connected to additional heat sinks. These may be copper foil areas on the p. c. board soldered to the tabs as shown in Fig. 16. The required side length of two identical square heat sink areas for an ambient temperature of $T_{amb} = 55\text{ °C}$ is shown in Fig. 9. The thickness of the copper layer 35 µm.

Procedure to calculate the area of copper needed

- 1) Calculate maximum power to be dissipated

$$P_{tot} = 0.4 \cdot \frac{(V_{Bmax})^2}{8 \cdot R_L} + V_{Bmax} \cdot \text{Quiescent current consumption}$$

where

V_{Bmax} = maximum value of supply voltage (increase by 10 % if not stabilized)

R_L = load resistance

The quiescent current consumption can be read from Fig. 8. For worst case calculations take the maximum value, 20 mA.

- 2) Fig. 16 gives the required side length l of one square copper foil area.

Examples

- a) $V_B = 24\text{ V}$ not stabilized, $R_L = 16\ \Omega$

$$P_{tot} = 0.4 \cdot \frac{(24 + 2.4)^2}{8 \cdot 16} + (24 + 2.4) \cdot 20 \cdot 10^{-3} = 2.6\text{ W}$$

Fig. 9 gives a side length of $l = 25\text{ mm}$ approximately.

For geometries different from the one of Fig. 16 note that copper areas near the tabs have better efficiency as regards power dissipation. Therefore additional safety factors must be added for worst case designs.

- b) $V_B = 12\text{ V}$ stabilized, $R_L = 8\ \Omega$

$$P_{tot} = 0.4 \cdot \frac{12^2}{8 \cdot 8} + 12 \cdot 20 \cdot 10^{-3} = 1\text{ W}$$

Fig. 9 shows that no heat sink is required if $T_{amb} \leq 55\text{ °C}$.

Controlled Pulse Generator for Thyristor Line Output Stages

The TBA 940 is an advanced version of the TAA 790. It comprises the sync separator with noise suppression, the frame pulse integrator, the phase comparator, a switching stage for automatic changeover of noise immunity, the line oscillator with frequency range limiter, a phase control circuit and the output stage.

It delivers a prepared frame sync pulse for triggering the frame oscillator. The phase comparator may be switched for video recording operation. Due to the large scale of integration few external components are needed.

Design and Operation Mode

The sync separator separates the synchronizing pulses from the composite video signal (BAS signal). The noise inverter circuit, which needs no external components, in connection with an integrating and differentiating network frees the synchronizing signal from distortion and noise.

The frame sync pulse is obtained by multiple integration and limitation of the synchronizing signal, and is available at pin 7. The RC network hitherto required between sync separator and frame oscillator is no longer needed. Since the frame sync pulse duration at pin 7 is subject to production spreads it is recommended to use the leading edge of this pulse for triggering.

The frequency of the line oscillator is determined by a 10 nF Styroflex capacitor at pin 13 which is charged and discharged periodically by two internal current sources. The external resistor at pin 14 defines the charging current and consequently in conjunction with the oscillator capacitor the line frequency.

The phase comparator compares the sawtooth voltage of the oscillator with the line sync pulses. Simultaneously an AFC voltage is generated which influences the oscillator frequency. A frequency range limiter restricts the frequency holding range.

The oscillator sawtooth voltage, which is in a fixed ratio to the line sync pulses, is compared with the flyback pulse in the phase control circuit, in this way compensating all drift of delay times in driver and line output stage. The correct phase position and hence the horizontal position of the picture can be adjusted by the 10 k Ω potentiometer connected to pin 11. Within the adjustable range the output pulse duration (pin 2) is constant. Any larger displacements of the picture, e. g. due to non-symmetrical picture tube, should not be corrected by the phase potentiometer, since in all cases the flyback pulse must overlap the sync pulse on both edges (see Fig. 3).

The switching stage has an auxiliary function. When the two signals supplied by the sync separator and the phase control circuit respectively are in synchronism a saturated transistor is in parallel with the integrated 2 k Ω resistor at pin 9. Thus the time constant of the filter network at pin 4 increases and consequently reduces the pull-in range of the phase comparator circuit for the synchronized state to approximately 50 Hz. This arrangement ensures disturbance-free operation.

For video recording operation this automatic switchover can be blocked by a positive current fed into pin 8, e. g. via a resistor connected to pin 3. It may also be useful to connect a resistor of about 680 Ω or 1 k Ω between pin 9 and ground. The capacitor at pin 4 may be lowered, e. g. to 0.1 μ F. These alterations do not significantly influence the normal operation of the IC and thus do not need to be switched.

The output stage delivers at pin 2 output pulses of duration and polarity suitable for driving the line driver stage. If the supply voltage goes down (e.g. by switching off the mains) a built-in protection circuit ensures defined line frequency pulses down to $V_3 = 4\text{ V}$ and shuts off when V_3 falls below 4 V , thus preventing pulses of undefined duration and frequency. Conversely, if the supply voltage rises, pulses defined in duration and frequency will appear at the output pin as soon as V_3 reaches 4.5 V . In the range between $V_3 = 4.5\text{ V}$ and full supply the shape and frequency of the output pulses are practically constant.

TBA 950, TBA 950:F

Controlled Pulse Generators for Transistor Line Output Stages

Monolithic integrated circuit for pulse separation and line synchronization in TV receivers with transistor line output stage.

The TBA 950 is an advanced version of the TAA 790. It comprises the sync separator with noise suppression, the frame pulse integrator, the phase comparator, a switching stage for automatic changeover of noise immunity, the line oscillator with frequency range limiter, a phase control circuit and the output stage.

It delivers prepared frame sync pulses for triggering the frame oscillator. The phase comparator may be switched for video recording operation. Due to the large scale of integration few external components are needed.

The 950 is delivered in two groups having different output pulse durations. The TBA 950:F is designed for TV receivers according to the French standard.

TDA 1035

Sound Channel IC for TV Receivers

The TDA 1035 is a monolithic integrated circuit containing all stages required in the sound channel of a TV receiver. It is suitable for mains as well as battery-operated receivers and is contained in a plastic package similar to TO-116, with 13 connection pins. These pins are shaped and arranged in such a way that automatic application to printed circuit boards can be carried out without difficulty. The cooling tabs projecting from the case on either side are sufficiently large for a 2 W output power without additional heat sink facilities. If these tabs are cooled further, for example by being soldered to a sufficiently large copper-clad area of the printed circuit board, an output power of up to 4 W is permissible.

As can be seen from Figs. 2 to 4, the TDA 1035 requires only few external components. It consists of a limiting IF amplifier, a coincidence demodulator, an electronic volume control circuit and a complete AF amplifier with preamplifier, driver and output stage in series push-pull configuration. The IF section has excellent limiting properties and operates with high AM suppression. The coincidence demodulator supplies a low-distortion AF signal. For connection to a video recorder, the TDA 1035 is provided with a direct demodulator output which is not affected by the electronic volume control.

In order to receive signals from the AF output of a video recorder or from other AF signal sources, the TDA 1035 is provided with an AF input which can be influenced by the electronic volume control. A switching voltage allows the IF section to be switched off.

The output amplifier is protected against overheating. At a chip temperature of approximately 150 °C the AF voltage at the driver transistor is short-circuited.

TDA 1044, TDA 1044 F

Frame Scan Circuits for TV Receivers

The TDA 1044 is a monolithic integrated circuit containing all stages for the vertical deflection of 110° black and white TV receivers. The TDA 1044 F is intended for use in color TV receivers.

Both types comprise a linear sawtooth generator that can be synchronized with positive or negative pulses. The sawtooth generator receives its supply voltage separately via pin 12. By varying this supply voltage the amplitude of the sawtooth may be altered, so that a frame height control, e. g. coupled with the line width amplitude, may be realized. The internal geometric correction circuit, which can be matched to different screen radii by external resistors, does not require any external RC network and ensures tangential correction of the deflection current.

The integrated output amplifier of the TDA 1044 controls the deflection current and an integrated flyback booster circuit ensures low power dissipation of the device. The deflection current in color TV sets is controlled by a complementary pair of power transistors connected to the output of the TDA 1044 F. A negative feedback whose voltage is proportional to the deflection current ensures proportionality between sawtooth voltage and deflection current. In this way temperature dependent variations of the deflection coil resistance cannot affect the frame height and the NTC resistor hitherto connected in series with the deflection coil can be omitted.

The TDA 1044 operates within a supply voltage range of 11 V to 27 V. When operating the TDA 1044 F in connection with two power transistors (see Fig. 5) the supply voltage may be raised up to 42 V. In black and white TV receivers pin 6 of the TDA 1044 supplies positive blanking pulses with an amplitude of max. 20 V. In color TV receivers the TDA 1044 F supplies at pin 6 positive and at pin 7 negative blanking pulses.

¹⁾ Tangent correction can be made adjustable by potentiometers. The curvature of the deflection current S-curve may be changed by a series resistor connected to pin 1. The DC voltage at pin 1 is responsible for the up/down correction. This voltage derives from the supply voltage V_{12} and the divider ratio of the voltage divider at pin 12 and pin 1. If fixed resistors are used a ratio of approximately 1.45 for $R_{12/1}$ to $R_{1/13}$ should be observed.

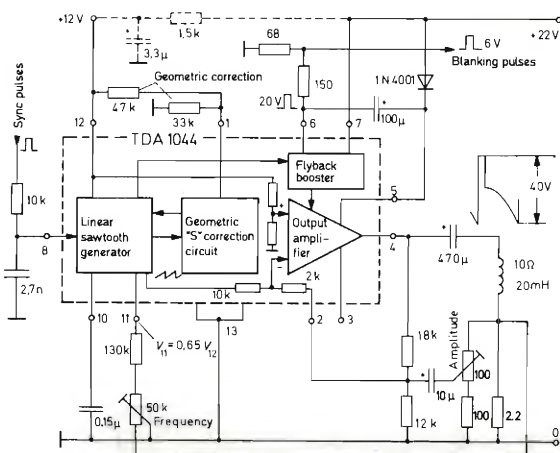

Fig. 3:

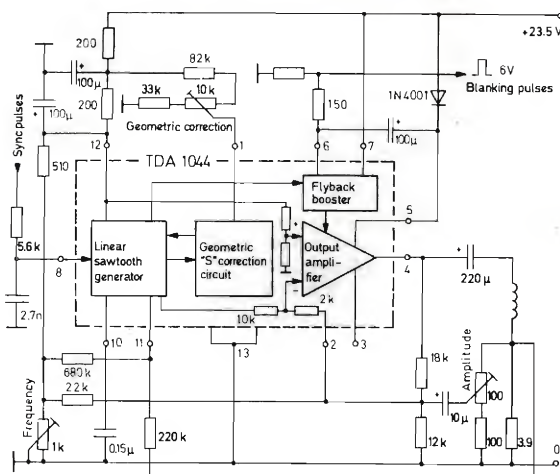

Fig. 4:
Application circuit for the TDA 1044 in black and white TV receivers showing a more extended frequency adjustment circuit. This ensures a constant vertical deflection current during any adjustment of the "Frequency" potentiometer.

TDA 1044, TDA 1044 F

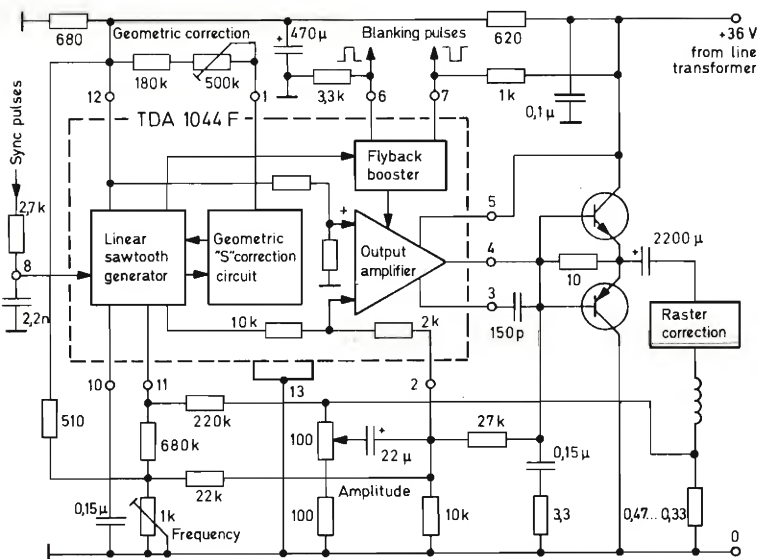

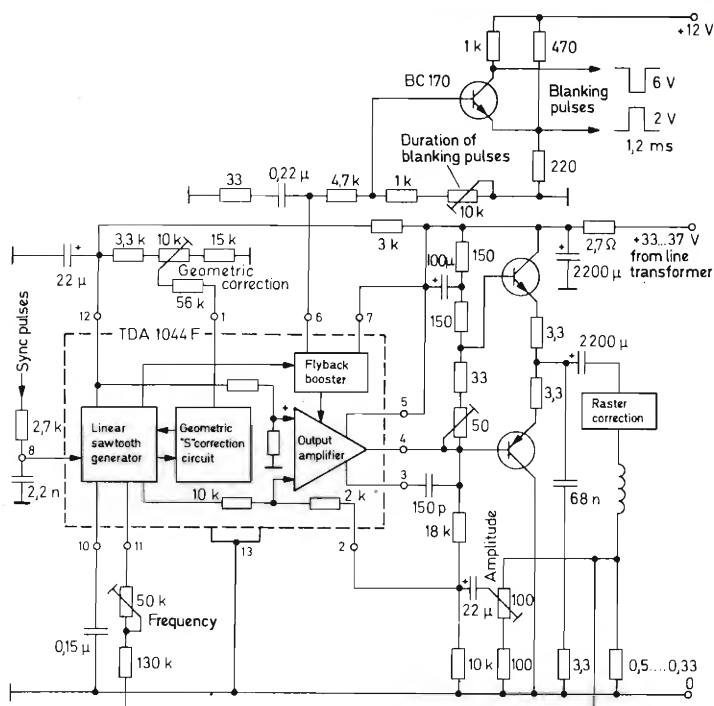

Fig. 5:

Application circuit for the TDA 1044 F in color TV receivers. The geometric correction circuit is designed for picture tubes type 20 AX and must be modified for different types. The picture height is not influenced by the adjustment of the "Frequency" potentiometer. The duration of the blanking pulses is equal to the flyback duration and therefore depending on resistance and inductance of the deflection coil. The 150 pF capacitor at pin 3 and pin 4 and also the Boucherot circuit $0.15 \mu\text{F}/3.3 \Omega$ at pin 4 and GND prevent any parasitic oscillation of the output amplifier. Dimensioning depends on the relation L/R of the vertical deflection coil. The higher this relation the more compensation (more capacitance and less resistance) is required. Both compensations are not required with usual black and white deflections coils.

**Fig. 6:**

Application circuit for the TDA 1044 F in color TV receivers. The geometric correction circuit is designed for picture tubes type 20 AX and must be modified for different types. For the compensation network at pin 3 and the output the legend of Fig. 5 is also valid. A pulse shaper containing a transistor BC 170 is connected to pin 6. This circuit ensures a constant duration of the blanking pulses (approximately 1.2 ms) independent of the flyback duration and the L/R relation of the vertical deflection coil.

TDA 1044, TDA 1044 F

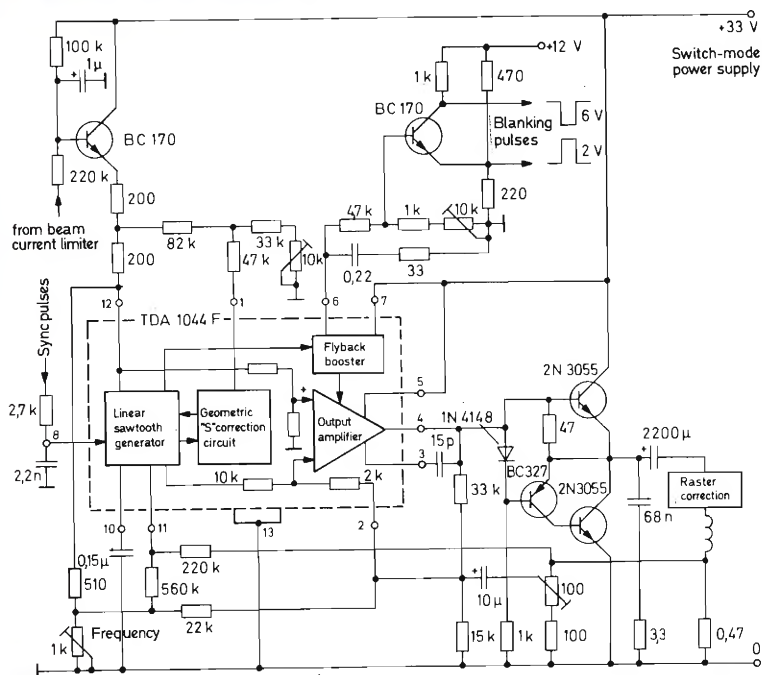

Fig. 7:

Application circuit for the TDA 1044 F in color TV receivers. The geometric correction circuit is designed for in-line picture tubes and must be modified for different types. For the compensation network at pin 5 and at the output the legend of Fig. 5 is also valid. A pulse shaper as described in the legend of Fig. 6 is connected to pin 6. Adjustment of the "Frequency" potentiometer does not influence the picture height. Via a transistor BC 170 the beam current limiter influences the supply voltage of the sawtooth generator at pin 12 and subsequently the picture height. Higher beam current results in a lower high-tension and enlarged picture (at constant deflection current). Reducing the oscillator amplitude via the supply voltage at pin 12 keeps constant the picture height.

TDA 1053

PIN Diode π Network

The TDA 1053 comprises in one plastic package three silicon planar PIN diodes connected to form a π network and serves for the electronic amplitude control of the input signals of TV tuners and antenna branching amplifiers in the 40...1000 MHz range. Both, its input and its output impedances remain constant over the entire control range.

The TDA 1053 is normally supplied with vertical leads, indicated by an additional "A" to the type designation. Upon special request it is also available with horizontal leads, add suffix "B" to the type No. The ratings stated overleaf apply to devices with vertical leads.

TDA 9400, TDA 9500

Line Circuits for TV Receivers

Monolithic integrated circuits for pulse separation and line synchronization in TV receivers. Both types are identical except the output stages and the shape of their output signals. The TDA 9400 shows a Darlington emitter follower output stage (see Fig. 1), the output signal of which is suitable for driving thyristor line output stages. The output stage of the TDA 9500 (see Fig. 3) supplies signals qualified for driving transistor line output stages.

Being advanced versions of the well-known types TBA 940 and TBA 950, the new types TDA 9400 and TDA 9500 comprise the sync separator with internal noise suppression, the frame pulse integrator, the phase comparator, a switching stage for automatic changeover of noise immunity and change of the slope of the phase control circuit, the line oscillator with frequency range limiter, a highgain phase control circuit, a stage for generating the burst gate pulses in colour TV receivers, an under-voltage protection circuit and — as mentioned above — different output stages.

Due to the large scale of integration only few external components are needed. These ICs deliver prepared frame sync pulses for triggering the frame oscillator (e.g. The TDA 1044 manufactured by INTERMETALL). Their phase comparator may be switched for video recording operation. A terminal (pin 14) for phase correction with the aid of the frame parabola is provided.

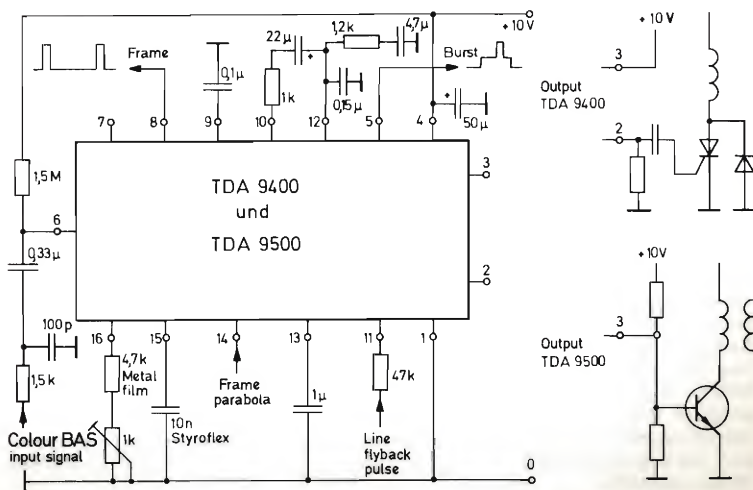

Fig. 5: Operating circuit of the TDA 9400 and TDA 9500

TDA 9400, TDA 9500

Design and Operation Mode of TDA 9400 and TDA 9500

The sync separator separates the synchronizing pulse from the composite colour video BAS signal. The noise inverter circuit, which needs no external components, and an internal gate-circuit free the synchronizing signal from distortion.

The frame sync pulse is obtained by internal integration and limitation of the synchronizing signal, and is available at pin 8.

The frequency of the line oscillator is determined by a 10 nF Styroflex capacitor at pin 15 which is charged and discharged periodically by two internal current sources. The external resistor at pin 16 defines the charging current and consequently in conjunction with the oscillator capacitor the line frequency.

The phase comparator compares the sawtooth voltage of the oscillator with the line sync pulse. Simultaneously an AFC voltage is generated which influences the oscillator frequency. A frequency range limiter restricts the frequency holding range.

The oscillator sawtooth voltage, which is in a fixed ratio to the line sync pulses, is compared with the line flyback pulse in the phase control circuit, in this way compensating all drift of delay times in driver and line output stage. The normal phase position is obtained if pin 14 is left vacant. Any phase displacement can be corrected by a current or voltage fed into pin 14. The duration of the output pulse is thereby not influenced.

The burst gate pulse is derived from the sawtooth voltage of the line oscillator and therefore via the phase comparator synchronized with the line sync pulses of the colour video signal.

The switching stage has different functions. When the two signals supplied by the sync separator and the phase control circuit respectively are in synchronism a saturated transistor is in parallel with the integrated 2 k Ω resistor at pin 10. Thus the time constant of the filter network at pin 12 increases and consequently reduces the pull-in range of the phase comparator circuit for the synchronized state. This arrangement ensures disturbance-free operation. Moreover, because the internal noise suppression and the internal gate circuit in synchronized operation are effective, the noise limitation is improved.

For video recording operation the automatic switchover can be blocked by a positive current fed into pin 9, e. g. via a resistor connected to pin 3. This reduces the time constant at pin 12 and increases the control current of the phase comparator thus steepening the static slope of the phase comparator which gives optimized matching in video recording operation.

The two types TDA 9400 and TDA 9500 have different output stages and different output pulse shapers. The output stage of the TDA 9400 is a Darlington emitter follower. This stage is suitable for directly driving the line deflection thyristor whereby an output current up to 600 mA is permitted, and the output stage is short-circuit protected. The output transistor of the TDA 9500 is operated in common emitter configuration. Its output current is limited to 50 mA by the pull-up resistor between pin 3 and the supply voltage. This current serves for driving the line deflection driver transistor.

If the supply voltage goes down (e. g. by switching off the mains) a built-in

protection circuit ensures defined line frequency pulses down to $V_4 = 4\text{ V}$ and shuts off when V_4 falls below 4 V , thus preventing pulses of undefined duration and frequency. Conversely, if the supply voltage rises, pulses defined in duration and frequency will appear at the output pin as soon as V_4 reaches 4.5 V . In the range between $V_4 = 4.5\text{ V}$ and full supply voltage the shape and frequency of the output pulses are practically constant.

ICs for Electronic Clocks

SAJ 300 R

CMOS circuit for RF Quartz Clocks with Digital Adjustment and 0,5 Hz Output

The monolithic integrated CMOS circuit SAJ 300 R is intended for use in crystal-controlled clocks operating on 12 V (6 ... 16.5 V) supply voltage.

It comprises an oscillator circuit, a fixed 4 : 1 frequency divider, a variable 2²¹ stage divider with an adjustment range of 2²¹ : 1 to (2²¹ + 2⁹) : 1 and a motor driver stage. An integrated Zener diode with approximately 17 V operating voltage protects the IC against voltage peaks on the supply voltage.

Apart from the crystal the oscillator requires no additional components. The trimmer capacitor previously needed for frequency adjustment has been omitted and this simplifies the layout of the clock. The function of the trimmer capacitor has been taken over by the variable frequency divider comprised in the IC and used to set the correct output frequency. For this purpose, seven adjustment terminals are provided on the SAJ 300 R: they are used to set the divider ratio to the required value with an accuracy of 10⁻⁶. With an oscillator frequency of 4.194812 MHz, the series-connected push-pull output stage supplies a symmetrical square wave signal with a pulse duty factor of 0.5 and a repetition frequency of 0.5 Hz if the variable frequency divider is set to the centre. Due to the differentiating effect of the motor capacitor pulses of alternate direction and one second distance originate in the motor coil.

The adjustable frequency divider has been designed in such a way that the maximum output frequency is set when all adjustment terminals are either open-circuit or connected to pin 14. If one or more adjustment terminals are grounded (taken to pin 13), the output frequency decreases. Pin 7 gives the smallest adjustment of 1.9 ppm. Pin 6 affords the next-larger step of 3.8 ppm and so forth, up to pin 1 which enables an adjustment step of 122 ppm to be obtained. Thus, if all adjustment terminals are grounded, the output frequency is reduced by 242 ppm.

The by-four-divided oscillator frequency may be checked at a separate test terminal M (pin 8) non-reactive with respect to the oscillator. Based on this check the output frequency and consequently the accuracy of the clock may be adjusted at the terminals 1 ... 7 by means of the variable frequency divider.

SAJ 300 T

CMOS Circuit for RF Quartz Clocks with Digital Adjustment and 64 Hz Output

The monolithic integrated CMOS circuit SAJ 300 T is intended for use in crystal-controlled clocks operating on 12 V (6...16.5 V) supply voltage. It comprises an oscillator circuit, a fixed 4:1 frequency divider, an adjustable frequency divider and a motor driver stage. The adjustable frequency divider may be adjusted in 127 steps, covering the range from $2^{14}:1$ to $(2^{14} + 2^2):1$.

Apart from the crystal the oscillator requires no additional components. The trimmer capacitor previously needed for frequency adjustment has been omitted and this simplifies the layout of the clock. The function of the trimmer capacitor has been taken over by the variable frequency divider comprised in the IC and used to set the correct output frequency. For this purpose seven adjustment terminals are provided on the SAJ 300 T: they are used to set the divider ratio to the required value with an accuracy of 10^{-6} . With an oscillator frequency of 4.194 812 MHz, the series-connected push-pull output stage supplies a symmetrical square wave signal with a pulse duty factor of 0.5 and a repetition frequency of 64 Hz if the variable frequency divider is set to the centre. Due to the differentiating effect of the motor capacitors pulses of alternate direction and 7.8 ms distance originate in the motor coil.

The adjustable frequency divider has been designed in such a way that the maximum output frequency is set when all adjustment terminals are either open-circuit or connected to pin 14. If one or more adjustment terminals are grounded (taken to pin 13), the output frequency decreases. Pin 7 gives the smallest adjustment of 1.9 ppm. Pin 6 offers the next larger step of 3.8 ppm and so forth, up to pin 1 which enables an adjustment step of 122 ppm to be obtained. Thus, if all adjustment terminals are grounded, the output frequency is reduced by 242 ppm.

The by-four-divided oscillator frequency may be checked at a separate test terminal M (pin 8) non-reactive with respect to the oscillator. Based on this check the output frequency and consequently the accuracy of the clock may be adjusted at the terminals 1...7 by means of the variable frequency divider.

TCA 860

Driving Circuit for Clocks with Single-Coil Balance Systems

This monolithic integrated circuit in bipolar technique is intended for driving clocks (wall and table models) with single-magnet, single-coil balance systems.

The TCA 860 simplifies the design of the clock circuitry and stabilizes the balance wheel amplitude against external mechanical influences as well as against supply voltage changes.

The circuit is operated from a conventional battery. Its current consumption is low.

Ambient operating temperature range	T_{amb}	- 10 ... + 60	°C

Recommended Operating Conditions

Supply voltage	V_B	1.5 (1.1 ... 1.65)	V
Frequency of driving pulses	f_A	5 (2 ... 8)	Hz
Capacitor	C_1	0.22 (0.1 ... 0.33)	μF
	C_2	15 (10 ... 22)	μF
Induced voltage at nominal amplitude	V_{ins}	550	mV
Coil resistance	R_L	250 (200 ... 300)	Ω
Discharge resistor	R_C	180	k Ω

Test Conditions for the Characteristics

The characteristics of the TCA 860 are tested by a method which is independent of the properties of a particular clock mechanism. For this reason, the multivibrator properties of the TCA 860 are utilised in the test circuit as shown in Fig. 4. The pulse frequency of the circuit (Fig. 5) is inversely proportional to the value of capacitor C_2 . It should be chosen so that automatic test equipment may be used.

Operation as Multivibrator

 $C_1 = 0,1 \mu\text{F}$, $C_2 = 1 \mu\text{F}$, $T_{amb} = 25 \text{ }^\circ\text{C}$

Duration of period	t_m	40 ... 90	ms
Pulse duration	t_d	4,5 ... 16	ms
Saturation voltage	V_{3sat}	< 250	mV

Hints for the Design of Circuits with TCA 860

The optimum conditions for the driving pulse exist when it ends before the induced voltage approaches zero. This condition depends on the choice of capacitance C_2 , the discharge resistance R_C , and the properties of the movement such as induced voltage $V_{in s}$, driving frequency f_A , pulse duty factor t_i/T_A and coil resistance R_L .

The value of capacitance C_1 must be large enough to cut the voltage peaks caused by the coil inductance at steady state operation to a level less than the maximum value of the coil voltage v_3 (Fig. 3).

In order to ensure optimum amplitude control of the TCA 860 the positive voltage pulse must occur before the negative pulse as shown in Fig. 3.

The self-starting properties of an oscillating system depend mainly upon the characteristics of the balance system and the coil. The starting time is determined by the moment of inertia of the balance wheel, the magnet system, the value of the induced coil voltage and the coil resistance.

ambient temperature

These two curves were derived from measurements on a typical clock.

ICs for Motor Vehicles

SAK 215

Pulse Shaper for Revolution Counters

The monolithic integrated circuit SAK 215 is designed for use in revolution counters of cars and for other applications like frequency to current converters. By use of suitable external circuitry the revolution counter can be adapted to engines with two to eight cylinders. It is designed for a nominal 12 V DC supply.

Fig. 1 shows the operating circuit of a revolution counter with FSD = 6000 RPM (two ignition pulses per turn of the crank-shaft) at a nominal battery voltage of 12 V.

Output current	I_5	$-I_6$	

Fig. 3: Test circuit for the characteristics

Dimensioning Hints

Coil resistance R_M of the indicating instrument

The output transistor must operate in the active range. This is ensured if

$$V_{5/6} = V_7 - V_6 - (I_{5p} \cdot R_M)$$

is above 1 V. The additional inductive voltage drop at the beginning of a current pulse due to the inductance of the moving coil is ignored in this equation.

Adjustment resistor $R_{6/1}$ for the instrument current

The peak current through the moving coil is given at a pulse duty factor of 0.7 by

$$I_{5p} = \frac{I_M}{0.7}$$

where I_M is the DC current for full scale deflection. Since the current flowing into pin 5 is equal to the sink current of pin 6 the adjustment resistor $R_{6/1}$ can be calculated as

$$R_{6/1} = \frac{V_6}{I_{5p}}$$

Series resistor R_V

Between pin 7 and pin 1 the circuit behaves like a zener diode. The resistor R_V therefore has to be chosen so that adequate current for the IC and the moving coil is available even at the lowest battery voltage:

$$R_V \leq \frac{V_{B \min} - 8.2 \text{ V}}{12 \text{ mA} + I_{5p}}$$

By-pass resistor $R_{7/8}$

In order to ensure proper function of the stabilizing circuit the voltage drop across the by-pass resistor $R_{7/8}$ must be limited to 7 V at the highest battery voltage.

$$R_{7/8} < \frac{7 \text{ V} \cdot R_V}{V_{B \max} - 7.4 \text{ V}}$$

SAY 115 X, SAY 115 Y

Speedometer and Mileage Indicator

The monolithic integrated circuit SAY 115 is designed for use in electronic speedometer and mileage indicator systems in automobiles.

It comprises a monostable flip-flop with Schmitt trigger input and an output stage comprising a current source whose current is indicated by a moving coil instrument (see Fig. 1). A binary frequency divider followed by a doubled output stage controls a stepping motor with two windings for mileage indication. The frequency divider of the SAY 115 X consists of five and at the SAY 115 Y of six stages. An analogue output controlled by the monostable flip-flop may be used to obtain an additional signal when an arbitrarily selected speed is exceeded or when the speed falls below the desired level.

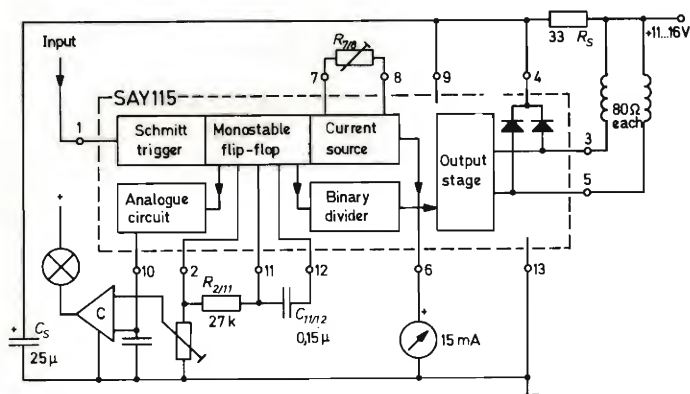

Fig. 1: Circuit of an electronic speedometer with FSD at $f_i = 300 \text{ Hz}$

Fig. 2:
SAY 115 in dual in-line
plastic package

Weight approx. 1.5 g
Dimensions in mm

The input signal for the SAY 115 is preferably derived from the gearbox via a reed contact, a make-and-break oscillator or an inductive sensor. The monostable flip-flop is triggered during the trailing edge of the input signal; a possible bouncing of the grounded reed contact can therefore not produce faulty indications, since such bouncing coincides with the metastable period of the flip-flop. The shape of the input pulses is irrelevant, provided that the predetermined upper and lower thresholds are reliably attained. The pulse duration produced by the monostable flip-flop is determined by the RC -network $R_{2/11}$, $C_{11/12}$. It is subject to variation within wide limits and capable of being adapted to the input frequency.

The mean output current from pin 6, which is a linear function of the input frequency, can be adjusted by using the trimmer potentiometer $R_{7/8}$. It is possible to use either $R_{7/8}$ or $R_{2/11}$ for calibrating the speedometer. Since the indicating instrument is supplied from a current source, temperature-dependent variations of the instrument coil resistance do not affect the indication. The temperature response of the indication is determined only by the components $R_{2/11}$, $R_{7/8}$ and $C_{11/12}$, since the drift of the current source is negligible. As a result, there is virtually no warm-up error that can affect the indication when the supply voltage is turned on. One terminal of the moving coil instrument is grounded which simplifies the mechanical layout.

If a filter capacitor is added to the analogue output, a DC voltage is obtained which is a linear function of speed. Using a comparator C, an alarm signal can be produced when the speed exceeds or falls below an arbitrarily chosen value. The reference voltage needed for the second comparator input may be derived by means of a voltage divider (trimmer potentiometer) from the stabilised 6.5 V available at pin 2. The level of the switching threshold in this arrangement depends only upon the temperature response of the comparator, the voltage divider and the RC network $R_{2/11}$, $C_{11/12}$.

The binary divider of the SAY 115 X consists of five stages (dividing the input frequency by $2^5 = 32$) and the divider of the SAY 115 Y consists of six stages (dividing factor $2^6 = 64$). The reduced frequency drives the double output stage, each part consisting of an NPN Darlington pair. One of the two output stages is always low and the other one high in turn of any half-period of the output signal. Each output is provided with an integrated free-running diode, whose cathodes being connected to pin 4.

In order to protect the integrated circuit against high voltage peaks from the car supply system, an external filtering network for the supply voltage must be provided. The motor supply current does not flow through the resistor of the filtering network; reliable starting of the stepping motor is thus ensured even in the case of low battery voltages. The cooling fins of the package (pin 13) form the ground pin of the SAY 115; they must be soldered to the copper layer of the printed circuit board in such a way that good heat conduction is achieved.

All voltages are referred to pin 13 (ground).

TCA 700 X

Car Voltage Stabilizer

Monolithic integrated voltage stabilizer in bipolar technology, specially designed for stabilized power supplies of car instrumentation in vehicles with 12 V accumulators.

This IC features narrow tolerance on output voltage, a low temperature coefficient and is equipped with an automatic current limiter and a thermal overload protection which prevents destruction of the IC in case of accidental overloads, for example short-circuits. A sufficiently large cooling fin must be provided, to ensure that under normal working conditions the max. permissible junction temperature is not exceeded, and the thermal overload protection does not operate.

ICs for Electronic Organs

Seven Stage Frequency Divider in I²L Technique

triggerable by the positive flank of the input signal

Monolithic integrated circuit in I²L technique designed primarily for use in electronic organs. The device incorporates seven flip-flops with externally accessible inputs and outputs. It is pin compatible with the SAJ 110 seven stage frequency divider.

The individual flip-flops can be interconnected to form a divider chain. Some flip-flop stages are already internally series-connected as shown below. The SAA 1004-N may be driven by sinusoidal as well as by square-wave input signals. The flip-flops change state with each positive-going flank of the input voltage (see Fig. 3).

Special features are: low impedance push-pull outputs, high input impedance, low current consumption and wide supply voltage operating range.

SAJ 110

Seven Stage Frequency Divider

Monolithic integrated seven stage frequency divider in bipolar technique, primarily for use in electronic organs. The seven flip-flops have externally accessible inputs and outputs.

Each flip-flop changes state on application of a positive-going input pulse. The individual flip-flops can be interconnected to form a divider chain. Two flip-flop pairs are already internally series-connected as shown in Fig. 2.

An emitter-follower is interposed between each flip-flop and the associated output pin to ensure that the output voltage is largely independent of load. Because no internal emitter resistors are provided, the emitter-follower delivers unidirectional output currents.

When used in electronic organs the frequency divider SAJ 110 may be driven by sine wave as well as square wave signals. The shape of the square wave output signal can be modified by connecting *RC* filters.

If, by means of an appropriate circuit, all inputs and outputs are brought to a potential below 1.5 V for a short time, all outputs remain in the low state.

Output resistance low state	r_o	> 1	$\text{M}\Omega$
Output resistance high state	r_o	200	Ω

¹⁾ During resetting in accordance with Figs. 4 and 8 this value may be exceeded for a time less than 0.1 ms.

Recommended Operating Conditions

Supply voltage	V_7	9	V
Max. input frequency	f_{imax}	50	kHz
Load resistance	R_L	2 ... 20	k Ω

If the output voltage shape has to be modified for applications in electronic organs (see Fig. 3), a protective resistor $R_S = 180 \Omega$, connected in series with the capacitor C_L , should be used. In this case the condition $R_L \gg R_S$ must be met.

Fig. 3: Modification of square wave output voltage using RC networks

- a) Circuit diagram, D = Decoupling diode, e.g. BA 170
 b) Shape of output voltage V_{RL}

On application in counter circuits resetting may be required. This can be accomplished by bringing all outputs to a potential less than 3 V with the inputs kept at 0 V as shown in Fig. 8, or more conveniently by bringing all inputs and outputs to a potential less than 1.5 V. The active edge of the reset pulse has to be fast enough to complete the resetting within less than 0.1 ms, otherwise the device may be overloaded. Fig. 4 shows a recommended circuit for resetting.

TDA 0470-D

Gate for Electronic Organs

Pin compatible, improved version of the TDA 0470

Monolithic integrated circuit in bipolar technique, designed primarily for use in electronic organs. The device incorporates twelve transistors, each replacing a mechanical key-contact. Thus it is possible to reduce the numerous mechanical key-contacts on conventional organs (up to ten per key) to one single contact per key.

Each tone-signal to be switched may be fed into one of the twelve emitters as a driving current. The transfer of the different signals to the common collector is effected by DC voltages. The sum of all signals will be derived at pin 14.

The additional integrated clamping diodes limit the signal voltage at each emitter when the transistors are cut off thus reducing crosstalk via the capacitances of the blocked transistors.

ICs for Other Applications

SAH 215

Telephone Push-Button Dialling IC

Monolithic integrated circuit in MOS technique for use in telephone sets with dialling push-buttons.

Special Features:

The off-normal output is released during the inter digital pause

Decoding by means of ROM gives flexible code

Two different dial pulse ratios optional

Two different inter digital pauses optional

The SAH 215 — Design and Operation

This circuit makes it possible to design push-button dialling telephone sets for connection to conventional telephone networks (quickstep-dialling).

The MOS circuit requires a two-phase clock generator which delivers two non-overlapping clock pulses having an amplitude of approximately -18 V . Its power consumption can be kept to the extremely low value of less than 4 mW .

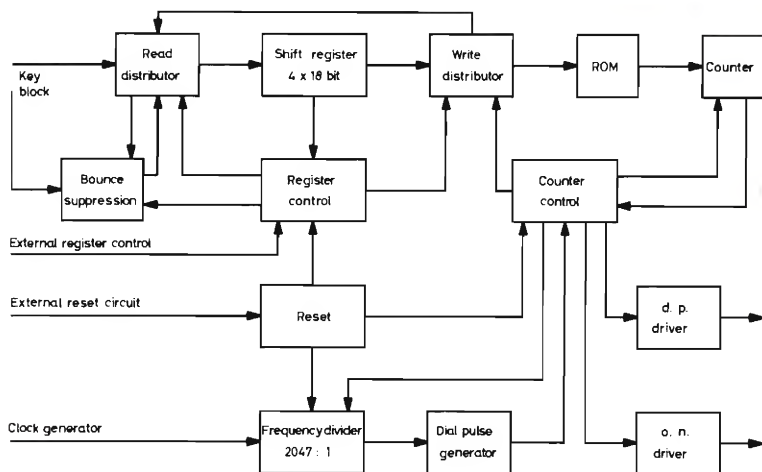

Fig. 2: Block diagram of the SAH 215

Fig. 2 shows the block diagram of the SAH 215. Four-bit data arriving from the key block are fed in parallel to the shift register via the read distributor. This register consists of four parallel individual registers of 18 bits each and serves for storing a maximum of 18 figures. A bounce-suppression circuit prevents a dialled figure from being written into the register more than once, due to contact bounce in the key block. The register control unit ensures the proper writing and reading sequence.

Through the write distributor the data are taken to a read only memory (ROM) which operates as a decoder and sets a counter in accordance with the entered figure. Through the counter control unit, the dial pulse generator transmits the number of pulses for which the counter was set to the d. p. (dial pulse) driver, maintaining the proper pulse duty factor. The counter control unit maintains the required interval between the several pulse trains and controls the o. n. driver.

The dial pulse generator frequency is derived from the clock frequency by means of a 2047:1 frequency divider. For the customary dialling frequency of 10 Hz the required clock frequency is therefore 20.47 kHz.

When applying the supply voltage to the MOS circuit, all stages of the control units have to be reset. This is achieved by a built-in reset unit which is controlled by an external circuit. The "0" → "1" slope of the reset signal must be at least 1 V/ms.

Fig. 3 shows a block diagram of the whole circuit arrangement.

Fig. 3: Block diagram of the general layout

The SAH 215 operates with the following code:

Figure	D	C	B	A
1	0	0	0	0
2	0	0	0	1
3	0	0	1	0
4	X	1	0	0
5	0	1	X	1
6	0	1	1	0
7	1	0	0	0
8	1	X	0	1
or 8	1	0	X	1
9	1	0	1	0
0	0	0	1	1

The information in this table relates to "negative logic", i. e. the more negative voltage level (Low) stands for logic "1", and the more positive voltage level (High) for logic "0". The symbol "X" may be an "0" or a "1" (see also page 12).

When using a key block in which each key is provided with two ordinary contacts and one positively controlled n. o. (non-overlapping) contact it is possible to control the integrated circuit directly. The same applies to a key block with row and column switches each of which is provided with a common positively controlled n. o. contact. The positively controlled n. o. contacts which close after the other n. o. contacts and open before the other n. o. contacts, control the strobe input 5. Key blocks of different design may be adapted by using a diode matrix. A general requirement for key blocks is that the data signals must be free from bounce prior to the strobe signal as each key is depressed.

Further possibilities of adaptation are introduced by mask variations which enable any desired four-bit code to be set, as long as the tetrads 1111 and 1110 do not occur, because they are needed for register control.

An additional facility

In normal use the terminal 6 is not loaded. This corresponds to a logic "1". If a logic "0" signal is applied to this terminal the register output is blocked and the data made to circulate in the register. In this way, up to 17 figures can be stored. By applying appropriate pulse patterns to terminal 6 individual figures or figure blocks may be recalled. The input of data is not affected by a signal being applied to terminal 6, so that the storage of figures can continue.

All voltages are referred to terminal 1.

Maximum Ratings

Drain voltage	V_{DD}	$-30 \dots +0.3$	V
Input voltage	V_{in}	$-30 \dots +0.3$	V
Clock pulse voltages	V_{t1}, V_{t2}	$-30 \dots +0.3$	V
Output current	I_o	-5	mA
Storage temperature range	T_S	$-40 \dots +100$	°C

Recommended Operating Conditions

Drain voltage	V_{DD}	-22 (-20 ... -24)	V
Clock pulse voltage (see Fig. 7)			
high state	V_{tH}	-1 ... +0.3	V
low state	V_{tL}	-18 (-17.5 ... -20)	V
Clock frequency (see Fig. 5)			
when $f_t > 2 f_{AFmax}$	$f_t = \frac{1}{T_t}$	40 (10 ... 500)	kHz
Clock pulse duration	t_1, t_2	> 0.8	µs
Interval between two clock pulses	t_{1p}, t_{2p}	> 0 (not overlapping)	
Signal pulse duty factor (see Fig. 8)	$\frac{t_1 + t_{1p}}{T_t}$	0.1 ... 0.9 ¹⁾	
Rise and fall time of the clock pulses	t_r, t_f	0.05 ... 10	µs
Input bias voltage	V_{in}	-8 (-7.5 ... -8.5)	V
Impedance of bias source at the input	$\frac{R_1 \cdot R_2}{R_1 + R_2}$	< 20	kΩ
Input signal amplitude (peak-to-peak, see Fig. 10)	V_{AFpp}	3 (0 ... 6)	V
Input impedance of the filter at output	R_{inF}	> 20	kΩ
Output DC current (current of the constant current source see Fig. 11)	I_o	0.5 ... 1.5 ²⁾	mA
Ambient operating temp. range	T_{amb}	-20 ... +60	°C

¹⁾ The output signal is proportional $\frac{t_1 + t_{1p}}{T}$, because during the time $t_1 + t_{1p}$ the AF signal appears at the output.

²⁾ If the filter input impedance R_{inF} exceeds 1 MΩ, the constant current source at the output may be replaced by a resistor $R_L > 10$ kΩ (see Fig. 12).

TCA 350 Y

Characteristics

at $V_{DD} = -22$ V, $V_{in} = -8$ V, $V_{AFPP} = 6$ V, $f_{AF} = 400$ Hz, $V_{IH} = 0$, $V_{IL} = -18$ V, $f_t = 40$ kHz, $t_1/T_1 = t_2/T_2 = 0.48$, $t_r = t_f = 2$ μ s, $I_o = 0.5$ mA, $T_{amb} = 25^\circ\text{C}$ in the circuit Fig. 1 which includes the Butterworth filter at the output. The latter has a cutoff frequency of 8 kHz, an input impedance of 43 k Ω and an attenuation of 110 dB at kHz. These test conditions apply equally to Figs. 3...12.

Delay time ($\tau = \frac{184}{2 \cdot f_t}$)	τ	2.3	ms
Attenuation ¹⁾	a	8.5 (< 10)	dB
Distortion factor	k	0.5 (< 3)	%
Noise voltage, peak-to-peak (see Fig. 6)	V_{Npp}	1.2 (< 2)	mV
Noise voltage, RMS value (see Fig. 6)	$V_{N\text{ RMS}}$	0.2 (< 0.35)	mV
Clock input capacitances	C_i	150	pF

¹⁾ In the test circuit the AF signal appears at the output only for the duration $t_1 + t_{1p} = T/2$. This amounts to a 6 dB attenuation. Only the residual 2.5...4 dB of the above quoted attenuation can be ascribed to the delay line.

Design and Operation Mode

Fig. 1 shows the circuit diagram of the TCA 350 Y and the external circuit components.

The output transistor T 187 requires a drain voltage of -22 V from which the necessary input bias of -8 V is produced by a potential divider. Connected to the source terminal of the output transistor T 187, which operates as a source follower, is a 0.5 mA constant current source which acts as a load resistance and caters for voltage variations from $+5$ V to -22 V at the output of the TCA 350 Y. This ensures distortion-free transmission of the two bands of the output signal (see Fig. 3).

Fig. 4 illustrates the time relationship between clock signal and output signal as scaled by the clock frequency. The information contained in the output signal appears during the onset of clock pulse t_1 and is maintained up to the onset of clock pulse t_2 . During t_1 the input information is scanned, i.e. the capacitor $C1$ absorbs the information via the turned-on transistor T1. Every subsequent clock pulse (t_1 as well as t_2) shifts this information into the next capacitor of the chain. With the 185th pulse (of which 93 pulses are t_1 and 92 pulses t_2) the information reaches the last capacitor of the chain, i.e. $C185$, and, after amplification, becomes available via the source-follower T187 at the output of the TCA 350 Y. As is apparent from Fig. 4, the information is preserved up to the onset of t_2 , although the signal voltage is raised by about 14 V after the expiry of t_1 .

In this way the lower signal band is produced during t_1 , and the upper signal band during t_{1p} . Which proportion of the intelligence is contained in the lower, and which in the upper signal band depends upon the ratio of the clock pulse duration t_1 to the clock pulse interval t_{1p} . Thus, if $t_{1p} = 0$ information is transmitted exclusively in the lower signal band.

The delay time of the bucket brigade circuit TCA 350 Y is calculated by using the following equation:

$$\tau = \frac{n}{2 \cdot f_i} = \frac{184}{2 \cdot f_i}$$

wherein n is the number of buckets in the chain (in the present case 184 because capacitor $C7$ does not contribute to the delay time).

The lowpass connected to the output of the TCA 350 Y filters the delayed signal V'_{AF} from the output signal of the TCA 350 Y which contains the clock voltage.

Duplex RF Delay Line

Monolithic integrated MOS circuit for the variable delay of video and RF signals. The TCA 380 operates on the bucket brigade principle. The "buckets" contained in the circuit are 2×190 small integrated MOS capacitors. The signal is advanced from one capacitor to the next at the rhythm of the clock frequency and is thus delayed. By varying the clock frequency the time delay can be altered. Being a duplex delay line, the TCA 380 comprises two bucket brigade circuits whose inputs and outputs are connected in parallel. The clock signal is applied to the two bucket brigades in antiphase. This type of circuit offers the advantage that attenuation and signal-to-noise ratio are better by 6 dB than in a single bucket brigade. Moreover, the duplex configuration permit of a higher upper-end limit frequency. Whereas with a simple bucket brigade the high-end limit frequency is equal to half the clock frequency, the high-end limit frequency in the case of the duplex circuit is theoretically equal to the clock frequency. Fig. 1 is a diagram of the internal TCA 380 circuit. $V_1 \dots V_4$ are the attenuation-compensating stages mentioned overleaf.

The attainable signal delay τ depends, according to the following equation, upon the number of stages n and upon the clock frequency f_t :

$$\tau = \frac{n}{2f_t} = \frac{190}{2f_t}$$

By varying the clock frequency between the values $f_{t \min}$ and $f_{t \max}$, we obtain the differential delay

$$\Delta\tau = \frac{n}{2} \cdot \left(\frac{1}{f_{t \min}} - \frac{1}{f_{t \max}} \right)$$

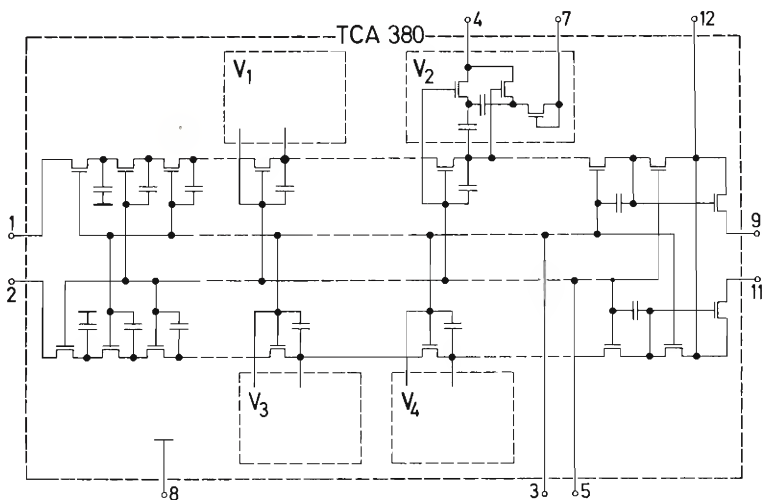

Fig. 1: Internal circuit of the TCA 380 (diagrammatic)

By means of likewise integrated attenuation-compensating stages, signal components of a higher frequency can be emphasised. This enables the frequency response of the delay line to be equalised by selecting the compensating voltage. If the clock frequency varies, the attenuation-compensating voltage may be varied in dependence on frequency.

It is advisable to let a lowpass filter precede the delay line whose upper cutoff frequency is lower than the smallest clock frequency $f_{t \min}$. Similarly, a lowpass filter should be included after the delay line which suppresses the clock signal superimposed on the intelligence signal.

Voltage Stabilizers for 5 ... 24 V

Monolithic integrated voltage stabilizers in bipolar technology for stabilizing voltages of 5 V to 24 V ($\pm 5\%$), with load currents of 500 mA to 200 mA, equipped with overload protection by current limiting with a reversing characteristic. When the excess load is removed the stabilized voltage returns by itself. Low drift, high stabilizing factor and low consumption in the non-operative condition are further features of these modern components.

The power to be dissipated can be calculated by the equation

$$P_{tot} = V_I \cdot I_{1r} + (V_I - V_3) \cdot I_3$$

From the maximum possible power the thermal resistance of the required cooling surface or radiator has to be calculated by the equation

$$R_{thS} = \frac{T_j - T_{amb}}{P_{tot}} - R_{thC}$$

Fig. 3: Output characteristic

UAA 210

Exposuremeter-IC

Monolithic integrated circuit in bipolar technology, for application in simple photographic cameras with fixed exposure time.

The UAA 210 comprises a window comparator with close tolerances and a 10 mA constant-current source supplying a light-emitting diode. Fig. 1 shows the application circuit. The photo-conductive element R_F , which is fitted beside the camera objective, measures the light impinging upon the camera and the light-emitting diode is extinguished when the correct stop has been set. Otherwise the stop, as well as a slide provided in front of the photoconductive cell and mechanically coupled to the stop will have to be displaced until the light-emitting diode is extinguished.

The characteristic of the window comparator (Fig. 4) is chosen in such a way that the indicator lamp is extinguished for a range comprising one light value, i. e. the maximum exposure error can only amount to one light value. Below a predetermined battery voltage, the light-emitting diode receives no current, which amounts to a voltage deficiency check within the UAA 210.

Glass case JEDEC DO-35
54 A 2 according to DIN 41 880
Weight approximately 0.13 g
Dimensions in mm

Maximum Ratings

Operating current	see table on next page		
Inverse current	I_F	100	mA
Power dissipation at $T_{amb} = 25^\circ\text{C}$	P_{tot}	350 ¹⁾	mW
Junction temperature	T_j	150	$^\circ\text{C}$
Storage temperature range	T_S	-55	+150 $^\circ\text{C}$

Characteristics at $T_{amb} = 25^\circ\text{C}$

Forward voltage at $I_F = 10\text{ mA}$	V_F	< 1.1	V
Temperature coefficient of the stabilized voltage at $I_Z = 5\text{ mA}$			
ZTE 1.5 and ZTE 2	α_{VZ}	-26	$10^{-4}/^\circ\text{C}$
ZTE 2.4 ... ZTE 5.1	α_{VZ}	-34	$10^{-4}/^\circ\text{C}$
Thermal resistance	R_{thA}	< 0.4 ¹⁾	$^\circ\text{C}/\text{mW}$
Junction to ambient air			

¹⁾ Valid provided that the leads are kept at ambient temperature at a distance of 8 mm from case

Type	Operating voltage at $I_Z = 5 \text{ mA}$ $V_Z \text{ V}$	Dynamic resistance at $I_Z = 5 \text{ mA}$ $r_{zj} \Omega$	permissible operating current at $T_{amb} = 25^\circ\text{C}^1)$ $I_Z \text{ max. mA}$
ZTE 1,5	1.35 ... 1.55	13 (< 20)	120
ZTE 2	2.0 ... 2.3	18 (< 30)	120
ZTE 2,4	2.2 ... 2.56	14 (< 20)	120
ZTE 2,7	2.5 ... 2.9	15 (< 20)	105
ZTE 3	2.8 ... 3.2	15 (< 20)	95
ZTE 3,3	3.1 ... 3.5	16 (< 20)	90
ZTE 3,6	3.4 ... 3.8	16 (< 25)	80
ZTE 3,9	3.7 ... 4.1	17 (< 25)	75
ZTE 4,3	4.0 ... 4.6	17 (< 25)	65
ZTE 4,7	4.4 ... 5.0	18 (< 25)	60
ZTE 5,1	4.8 ... 5.4	18 (< 25)	55

¹⁾ Valid provided that the leads are kept at ambient temperature at a distance of 8 mm from case.

ZTE 1,5... ZTE 5,1

Breakdown characteristics

at $T_i = \text{constant}$ (pulsed)

Breakdown characteristics

at $T_i = \text{constant}$ (pulsed)

Admissible power dissipation versus ambient temperature (see note 1) on page 181)

Dynamic resistance versus operating current, normalised

Dynamic resistance versus operating voltage

ZTK 6,8 . . . ZTK 33 (\approx TAA 550)

Temperature-Compensated Stabilizing Circuits

feature extremely short thermal run-in time

Monolithic linear integrated circuits producing an extremely constant temperature-compensated voltage, particularly suitable for stabilizing the tuning voltage in radio and TV tuners employing voltage variable capacitance diodes.

Glass case JEDEC DO-35
54 A 2 according to DIN 41 880

Weight approx. 0.13 g
Dimensions in mm

Type	Operating voltage at $I_Z = 5$ mA V_Z V	Dynamic resistance at $I_Z = 5$ mA r_{zi} Ω	maximum operating current ¹⁾ at $T_{amb} = 45^\circ\text{C}$ I_Z mA
ZTK 6,8	6.4 . . . 7.1	10 (< 25)	36
ZTK 9	9 . . . 10	10 (< 25)	27
ZTK 11	10 . . . 12	10 (< 25)	19
ZTK 18	16 . . . 20	11 (< 25)	13
ZTK 22	20 . . . 24	11 (< 25)	10
ZTK 27	24 . . . 30	12 (< 25)	8
ZTK 33 (\approx TAA 550)	30 . . . 36	12 (< 25)	7

admissible junction temperature	T_j	150	$^\circ\text{C}$
admissible storage temp. range	T_s	$-20 \dots +150$	$^\circ\text{C}$
Temperature coefficient of the operating voltage at $I_Z = 5$ mA ± 0.5 mA in the range of $T_{amb} = 20 \dots 60^\circ\text{C}$	α_{VZ}	-2 ($-10 \dots +5$) ¹⁾	$10^{-5}/^\circ\text{C}$
Thermal run-in time	t_{th}	20 ²⁾	s
Thermal resistance Junction to ambient air	R_{thA}	< 0.4 ¹⁾	$^\circ\text{C}/\text{mW}$

¹⁾ Valid provided that leads are kept at ambient temperature at a distance of 8 mm from the case.

²⁾ At the end of this time ΔV_Z has reached 90 % of its final value $\Delta V_{Z \max}$.
 $\Delta V_{Z \max} = |V_Z(\alpha) - V_Z(0)|$

where $V_Z(0) = V_Z$ in the instant of turn-on

and $V_Z(\alpha) = V_Z$ at thermal equilibrium.

Time dependence of ΔV_Z after turn-on for different distances between case and point of ambient temperature on the leads

Dynamic resistance versus operating current

Permissible operating current versus ambient temperature (see note 1) on previous page)

Change of temperature coefficient versus operating current

ITT Manufacturing

The integrated circuits for consumer applications described in this manual are only parts of the ITT Semiconductors' manufacturing programme. A wide range of monolithic integrated digital circuits in TTL and MOS technology as well as transistors, diodes, Zener diodes and rectifiers of outstanding quality are at your disposal for your designs and your production.

Worldwide basic research and specified development programmes at ITT factories guarantee the most modern production methods. Rational large scale production ensures constant high quality standard at reasonable prices.

ITT components are marketed worldwide. We are pleased to inform you of the address of your local ITT distributor.

For information about the following components ask for your manual:

TTL Digital Integrated Circuits

NPN and PNP Silicon Transistors

NPN and PNP Silicon High Frequency Transistors

Luminescent Diodes

Ge Diodes

Si Diodes

Si Capacitance Diodes

Si Zener Diodes

Si Rectifiers
